PRENTISS SELBY. - - Superintendent

Nevada Metallurgical Works.

NO. 23 STEVENSON STREET,

Near First and Market Streets, S. F.

[ESTABLISHED, 1869.]

A. LUCKHARDT.

B. SALAZAR.

Ores worked by any Process.

Ores Sampled.

Assaying in all its Branches.

Analyses of Ores, Minerals, Waters, etc.

Working Tests (practical) Made.

Plans and Specifications furnished for the most suitable Process for Working Ores.

Special attention paid to Examinations of Mines; Plans and Reports furnished.

C. A. LUCKHARDT & CO.,

(Formerly Hubn & Luckhardt).

Mining Engineers and Metallurgists.

JOHN TAYLOR & CO.,

IMPORTERS AND DEALERS IN

**Assayers' Materials,
MINE AND MILL SUPPLIES,**CHEMICAL APPARATUS AND CHEMICALS, DRUG-
GISTS' GLASSWARE AND SUNDRIES, ETC.118 and 120 Market Street and 15 and 17
California St., San Francisco.We would call the attention of Assayers, Chemists,
Mining Companies, Milling Companies, Prospectors, etc.,
to our full stock of Balances, Furnaces, Muffles, Crucibles,
Scorifiers, etc., including, also, a full stock of
Chemicals.Having been engaged in furnishing these supplies since
the first discovery of mines on the Pacific Coast, we feel
confident from our experience we can well suit the demand
for these goods, both as to quality and price. Our
New Illustrated Catalogue, with prices, will be sent on
application.Our Gold and Silver Tables, showing the value per
ounce Troy at different degrees of fineness, and valuable
tables for computation of assays in grains and grammes,
will be sent free upon application. Agents for the Patent
Plumbago Crucible Co., London, England.**JOHN TAYLOR & CO.**

Reference—Any first-class Engine or Machine Builder in
America. Address, 43 Sacramento St., S. F.**WANTED****TO BUY—A MINING PROPERTY.** California gold
quartz preferred. Don't want mine to stock, but to work
as an individual enterprise. Prefer to own property
alone, but might take a mine to develop for a controlling
interest.

Address "WILSON,"

Care Mining and Scientific Press.

San Francisco Pioneer Screen Works**J. W. QUICK, MANUFACTURER.**Several first premiums received
for Quartz Mill Screens, and Per-
forated Sheet Metals of every
description. I would call special
attention to my SLOT CUT and
SLOT PUNCHED SCREENS,
which are attracting much at-
tention and giving universal satis-
faction. This is the only estab-
lishment on the Coast devoted
exclusively to the manufacture of
Screens. Mill owners using Battery Screens extensively can
contract for large supplies at favorable rates. Orders solicited
and promptly attended to.

32 Fremont Street, San Francisco.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Abe Co., Black also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRANWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

DOW STEAM PUMP WORKS,

SAN FRANCISCO, CAL.

Compound Water Works Engines and Pumping Machinery
A SPECIALTY.

THE IMPROVED DOW STEAM PUMPS

— ARE ADAPTED TO —

BOILER FEEDING, FIRE PURPOSES,
MINING, HYDRAULIC WORK,
ARTESIAN WELLS,

And in fact Every Purpose for which

ECONOMICAL AND RELIABLE STEAM PUMPS
ARE REQUIRED.

Mining Share Market.

Some of the stock dealers think they can see signs of improvement in the market, but the signs are rather faint so far as the public can discover. In the middle mines of the Comstock they will now soon be able to do some active prospecting work. The new drifts on the 2800 level are first-class in every respect. That from the Combination west is fully eight ft wide, giving ample room for a double track, while that through the Hale and Norcross ground is seven ft wide, and will contain a double track. These broad drifts on the 2800 level constitute air galleries capable of conveying a great volume of air and thoroughly ventilating the whole level. The Hale and Norcross folks may now return and open out their ground in which they heretofore obtained such favorable prospects, and the Chollar and Potosi companies may explore their ground thoroughly in all parts; it will be remembered that even on the 2600 level they were not able to do much prospecting work. At the Sierra Nevada they have now just begun to crosscut on their 3000 level. Other crosscuts will also soon be started in the Sierra Nevada on this level, and also a west crosscut in the Union Con. In the old bonanza mines (the California and Con. Virginia) they will now soon be in a position, after several years of inactivity, to make extensive explorations in very promising ground. All the leading Gold Hill companies are now extracting sufficient ore to keep the several mills on the Carson river in full blast.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Bullion Shipments.

Horn Silver, April 9, \$12,000; Ontario, 9, \$4,318; Hanauer, 10, \$4,200; Crescent, 10, \$1,650; Horn Silver, 10, \$3,000; Ontario, 10, \$4,297; Alice, 10, \$94,726; Horn Silver, 11, \$12,000; Ontario, 11, \$4,105; Hanauer, 12, \$2,350; Horn Silver, 12, \$6,000; Ontario, 12, \$4,270. The banks of Salt Lake City report for the week ending April 9th, inclusive, the receipt of \$101,663 52 in bullion, and \$5,000 in ore; aggregate, \$106,663 52.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals of good vigor. A day at Woodward's Gardens is a day well spent.

MINING SHAREHOLDERS' DIRECTORY.

COMPILED EVERY THURSDAY FROM ADVERTISEMENTS IN MINING AND SCIENTIFIC PRESS AND OTHER S. F. JOURNAL

"Clean in Every Respect," Etc.

The Mining and Scientific Press, San Francisco, Dewey & Co., publishers. This is one of the best weeklies in the United States. It contains the usual mining news, a large amount of valuable reading, including frequent articles on the topography, geology, archaeology and natural history of California and the adjoining Territories. Its position is always in favor of good morals, and in fact the paper can be pronounced clean in every respect.—*American Antiquarian.*

The Tustin Windmill Horse-power and

Pumping Machine Works.

308 Mission Street, S. F., Cal.

By W. I. TUSTIN, Inventor and Patentee.

Send for Circular.

Successful Patent Solicitors.

As Dewey & Co. have been in the patent soliciting business on this coast now for so many years, the firm's name is a well-known one. Another reason for its popularity is that a great proportion of the Pacific coast patents issued by the Government have been procured through their agency. They are, therefore, well and thoroughly posted on the needs of the progressive industrial classes of this coast. They are the best posted firm on what has been done in all branches of industry, and are able to judge of what is new and patentable. In this they have a great advantage, which is of practical dollar and cent value to their clients. That is this understood and appreciated is evidenced by the number of patents issued through their SCIENTIFIC PRESS PATENT AGENCY (S. F.) from week to week and year to year.

A GOLDEN OPPORTUNITY!

EQUAL PARTNER WANTED.

For the State of California, to furnish means

...TO WORK THERE...

Best Amalgamator and Separator

Yet Invented. Patented Oct. 16, 1883.

Will work any material profitably it will pay to dig—Black Sand and Pulverized Free-milling Ore. Little water required; simple in construction; saves all the gold, loses no quicksilver, and requires but a small expenditure of money for immense returns. Investigate, and address the inventor,

GEORGE DEAN,

No. 44 South Morgan Street, Chicago, Ills.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 814 California street.

SURVEYORS—INVENTORS.

\$1,000 CHALLENGE!

**THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.**

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hunkley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we herewith state:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.,

Room 7—No. 109 California Street,
January 3, 1884.

SAN FRANCISCO, CAL.

PATTEN'S CONCENTRATOR AND AMALGAMATOR COMBINED.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

The undersigned is now located at the Etna Iron Works, 217 to 221 Fremont street, where he is building the above machines and prepared to fill orders, and guarantee them to do all that is claimed. Estimates given and orders promptly filled for all kinds of mining machinery.

C. W. PATTEN, 217 Fremont Street, S. F.

— TO —
**HYDRAULIC
MINERS:**

THE ABOVE CUT REPRESENTS OUR NEW IMPROVED GIANT, WHICH we recommend as being the Best Hydraulic Machine ever manufactured. They are SIMPLER, LIGHTER, CHEAPER AND MORE EASILY WORKED than any style heretofore made. The machine is fully protected by patents owned by us, and we will guarantee protection to our customers. Send for Circular and Price List.

HOSKIN BROS.,

MARYSVILLE.

CALIFORNIA

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

DUNHAM, CARRIGAN & CO., San Francisco, Cal.

PATENTED
Oct. 11, 1881.

NEVIN'S CELEBRATED

**Patent Ore Roasting and Chloridizing
FURNACE.**

Working up to 93 per cent. of Fire Assay, using 25 per cent. salt since July, 1882. **ALL LICENSES FOR USE FOR SALE, OR FURNACES CONSTRUCTED. Address R. A. NEVIN, Patentee, Etna Iron Works, 217 Fremont St., San Francisco, Cal.**

POWDER! POWDER! POWDER! A New Explosive!!

MORE POWERFUL THAN NITRO-GLYCERINE,

And Warranted Perfectly Safe.

THE VAN CAMPEN COMPOUND!

THE SAFEST AND BEST EXPLOSIVE IN THE WORLD!

H. D. VAN CAMPEN, the patentee, has been at work for many years to accomplish the work of inventing an explosive that would compete with nitro-glycerine and yet be safe to handle. He has finished his undertaking, and to-day has upon the market the safest and best explosive in the United States. We defy any explosive on trial to make us take back the above statement. Any person taking exceptions to our statements we will meet on trial, IN ANY KIND OF BLASTING.

FOR RAILROAD WORK, QUARRY WORK, OR MINING

Nothing can Compete with the Van Campen Compound.

It may be cut in pieces, stamped on the ground, jammed around, set on fire and burned up, and no explosion. **REMEMBER ITS SAFETY.** We will leave the buyer to be the judge, and by testing will prove all we claim. For Sale in car-load lots direct to the trade. **PRICES LOW AND GOODS WARRANTED.** Anyone wishing Compound, or further instructions, should correspond with

Iron and Machine Works.

MACBETH'S —PATENT— STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys. They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:-

MATHER LANE SPINNING Co. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,

For the Mather Lane Spinning Co. (Limited),

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

St. Louis, Mo., Sept. 23, 1883

Messrs. Adolphus Meier & Co., GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,
ANHEUSER-BUSCH BREWING ASSN.

OFFICE OF Supt of ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 24, we respectfully inform you that the three boilers built under your patents, under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

MINING MACHINERY.

Plants for Gold and Silver Mills, embracing the latest and most improved machinery and processes for base and free ores. Water Jacket Smelting Furnaces for silver, lead and copper ores, with new and important improvements, superior to any other make. Hoisting Works, Pumping Machinery, Chloridizing Furnaces, etc. We offer our customers the best results of thirty years' experience in this special line of work, and are prepared to furnish the most approved character of Mining and Reduction Machinery, superior in design and construction to that of any other make, at the lowest possible prices. We also contract to deliver, in complete running order, Mills, Furnaces, Hoisting Works, etc., in any of the Mining States and Territories. Estimates given on application. Send for illustrated Circular.

MINERS' HORSE WHIM.

ONE HORSE CAN EASILY HOIST OVER 1,000 LBS. at a depth of 500 feet. The Whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-timbers, thus avoiding all frame-work. When required, these whims are made in sections to pack on mules.

CALL AND SEE IT OR SEND FOR CIRCULARS.

F. A. HUNTINGTON, SAW, SHINGLE, AND QUARTZ MILL MACHINERY.

We Call Attention to the Following Testimonials as to the Capacity and Durability of the Centrifugal Roller Quartz Mill:

SAN FRANCISCO, Dec. 27, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—The four-foot Centrifugal Roller Mill, bought of you in August, 1882, for the Whidden Gold Mining Company, of Shingle Springs, has given entire satisfaction, both on our own and on custom work, saving from 85 to 90 per cent of the gold in the mill. In conclusion I will say that we are so well pleased with it that Mr. Whidden and myself are putting one of the same size on the Tohongo gold mine, near Ravenna, in Los Angeles county.

Yours truly, P. VEASEY,
34 California St., S. F.

FINE GOLD GULCH, Nov. 10, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—In reply to your inquiry concerning the working of your Centrifugal Roller Quartz Mill, I am pleased to say that I run one of them for seven months, doing custom work on different varieties of rock, and that the mill gave satisfaction in every respect, and did all that you claim for it.

Yours truly, BYRON JENNINGS.

GARIBALDI MINE, Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to yours of the 10th inst., I take pleasure in assuring you that your Centrifugal Roller Quartz Mill gives entire satisfaction, and I can heartily recommend it to mining men who want a cheap and efficient crusher.

Yours truly, E. I. PARSONS, Supt.

32 WASHINGTON AVENUE, S. F.

SAN FRANCISCO, Dec. 29, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: Having run one of your Centrifugal Roller Quartz Mills on sample lots of rock from more than twenty different mines, I must say that in every instance it has given the best of satisfaction in every particular; and I recognize its superiority over any other mill manufactured.

Very truly yours, D. O. MOWEY.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

F. A. HUNTINGTON, 45 Fremont St., San Francisco.

SEE SAMPLE LOTS OF ORE WORKED.

SEE WHERE A MACHINE CAN BE SEEN IN OPERATION.

CENTRIFUGAL ROLLER QUARTZ MILL.

The work done by the Centrifugal Roller Quartz Mill, during the past two years, on various mines and different kinds of rock, PROVES ALL THAT IS CLAIMED FOR IT, VIZ:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

SUNORA, CAL., Dec. 1, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR:—In reply to yours of recent date, inquiring about the Centrifugal Mill which I bought of you, I will say that I have run the mill four months on hard rock; and I take pleasure in adding that the mill has in every way given the best of satisfaction.

Yours truly, J. H. NEALE.

GARIBALDI MINE,
Calaveras Co., Cal., Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR:—In answer to your inquiry concerning the working of the five feet Centrifugal Mill, bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

Very truly yours, O. B. SMITH.

F. A. Huntington Esq., San Francisco, Cal.—
DEAR SIR—Your Centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Co. property at Shingle Springs, El Dorado Co., Cal., about four months, and it has done good and satisfactory work, a greater proportion of gold remaining in the mill than in the stamp battery.

FRED JONES, Supt.

HILBRETH RANCH, Fresno Co., Cal.,
January 11, 1884.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR:—In regard to your mill (Centrifugal Roller), I have crushed about 500 tons of rock in the mill, and am glad to say that it has given entire satisfaction, and can recommend it to the public as the most expeditious and least expensive method for crushing and milling ore that I have ever seen.

Truly yours,

THOS. HILBRETH.

— MANUFACTURERS OF —

Machine Tools, Hydraulic Machinery and PORTABLE FORGES,

18 & 20 Fell St., opp. cor. 10th and Market, San Francisco.

Awarded 1st Premium for Engine Lathe, and Special 1st Premium for Portable Forge

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

DISPLACEMENTS in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

On Rock Drills.

[Written for the Press by GEO. J. SPECHT, C. E., 418
California St., San Francisco.]

The History of Rock Drills.

A short time after Martin Weizel of Freiberg, in 1613, had introduced the system of boring and blasting rock by means of powder, Henry Huthmann of Stefeld in the Hartz advanced, in 1683, the idea of a drilling machine, after the principle of a ram. But no practical result came from this, as was also the case with the propositions of Gainschnigg, of Salzburg, in 1803, and those of Richard Trevithick, of Cornwall, in 1813. In 1844, the Englishman, Brunton, proposed to use compressed air to work a hammer, striking a drill at the rate of 260 blows a minute, stating that the compressed air escaping from the drills would also ventilate the mine. But he did not succeed very well. In 1851, Mr. Cave of Paris, took up Brunton's idea and constructed a drilling machine worked by compressed air. The then proposed construction of the Mont Cenis tunnel gave a lively stimulus to inventors in this line. Bartlett of England in 1854, Colladou of Switzerland, in June, 1855, and Schuhmann of Germany, also in 1855, finally carried the idea to work drilling machines by compressed air to success. They were soon followed by Castelain, Schwarzkopf (1857), Sommeiller, Crattoni, and Grandis, and Haupt (1858), who tried his invention at the Hoosac tunnel. From then until now a very large number of inventions referring to rock drills have been patented all over the world. In the United States not less than 243 patents having been granted. With a few exceptions—notably the diamond drill—all these machines are so-called percussion drills.

Machine Drills in the United States.

In the United States the first power drill was a hand drill, invented by John Singer, and used for a period of four years, from 1838 to 1842, in the construction of the Michigan and Illinois canal; it was also used in the enlargement of the Erie canal, and in the cut through Mount Washington (Western railroad of Massachusetts.) The next important invention was the steam drill of J. Couch and Joseph W. Fowle, Boston, patented in 1848. They, however, did not meet with great success. From that time to 1861, when machine drills were used at the Mont Cenis tunnel, the inventors neglected this kind of machines. But the favorable result obtained in that tunnel caused the contractors of the Hoosac tunnel to investigate the question more thoroughly. They found the Sommeiller machine, used at the Mont Cenis not well adapted to their work, therefore bought the Fowle & Couch patent and engaged several

engineers to construct a machine suitable for their work. The result was the invention of a large number of machines. The first one tried was that of Hanson, which used the principle of the Couch drill, but did not meet with success, as it was too complicated.

First Burleigh Drill.

The only invention which proved to be of practical value was that of Brooks, Burleigh & Gates. Ten of these drills were used in sinking the central shaft and 30 in the headers. But the repairs were too many, so, for instance, for several months each and every machine had to be repaired once each day. The official re-

ports of the cylinder, the striking of the piston against the cylinder head being prevented by rubber rings or similar devices.

No Principal Differences in the Various Percussion Drills.

There is no characteristic difference in the principle of the various percussion drills, and in spite of the many improvements in the details, the more solid and exact construction and the simplification and the reduction of the number of parts, none of the various percussion drills have been able to drive its competitors out of the field.

The different systems, therefore, depend for

sary than if a quiet pressure be used instead. He proves the truth of this by an account of a number of experiments, which show the proportion between the effect of pressure and blow to be in an average—1 to 7.] Compressed air as a motive power is very expensive, in reference to the plant necessary to create it as well as to the running expenses. These three points, the many repairs necessary, the small useful effect and the expense of compressed air as a motive power, are disadvantages, which are natural with the percussive system and cannot be avoided by whatever ingenious inventions and improvements. They are the natural weaknesses of the system. The percussive system is in fact only an imitation of the human hand drilling. The system of the future has to abandon this path and must be based upon more correct principles. This has been done by Alfred Brandt in his hydraulic rock drill, an engraving of which is given on this page. This invention marks a new epoch in the history of rock drills.

The Various Motive Powers Used.

The application of steam directly to rock drills is only practicable in open cuts, quarries, short tunnels and shallow shafts, but not in more extensive underground workings. It, therefore, is rarely used, and does not need to be considered here.

Compressed air is at present the most generally used motive power. The principal advantages claimed for the same are that it affords a good ventilation of the underground workings by the escape of air from the drills, and that its use all through the mine or tunnel is exceedingly handy.

The last claim is undoubtedly true, especially when compared with the direct use of steam. But it is different with the first one. The air escaping from the drills assists the ventilation only while the drilling is going on, but not then, when fresh air is most needed, i. e., after blasting. And even during the drilling the escape of compressed air is by no means sufficient to supply all the needed ventilation. An extra supply of fresh air has to be provided for, which is either done by opening the main air pipe after the drilling has been finished, or by a separate ventilation. The first being an exceedingly expensive and inefficient way, will hardly ever be employed, while the second is generally used, because necessity dictates it. The percussion drills have this in common with any other system of drilling. The useful effect of an air compressor is not more than from 27 to 37 per cent. Therefore, to obtain better and more economical results, it is necessary to find another power.

High tension, the pressure varying from 350 to 700 lbs., is used in his rock drills water under

(CONTINUED ON PAGE 289.)

THE BRANDT HYDRAULIC ROCK DRILL AS SEEN IN OPERATION.

port about the progress of the tunnel says that since the introduction of machine drilling the road leading to the tunnel was crowded by a continuous line of laborers, each of them carrying a piece of the drill to or from the repair shop. After a few more months machine drilling was abandoned, until in 1866 the then greatly improved Burleigh drill, almost identical to the present construction, was introduced. They worked on an average 5 days without requiring any repairs, although some remained good for several weeks. From that time on to today a very large number of inventors have patented drills or parts of drills. The principle of all these machines (except the diamond drill) is the same, namely, percussion. All have a massive piston of steel, which throws the drill bit, directly connected with it, against the rock and withdraws it again; all have a more or less simple valve motion to distribute the steam or compressed air. The setting of the drill bit is done by letting the entire piston slide back on a rifle bar; the feed is either automatic or by hand. A review of the American rock drills shows the endeavor to construct a machine as simple and as durable as possible, to lay all movable parts, such as the valve motion, the setting and feeding mechanism, inside of the cylinder or shell, so that they cannot be injured by falling rocks or other accidents, and to decrease the clearance space by shortening

their sale mostly upon the ability of their agents to present their claimed advantages to the public. But none of these can attain such a superiority that the purchaser would select it as the best under all conditions. None of the great tunnels and mines, where nearly each and every kind of percussion drills has been used and experimented with, have been able to award the prize of undisputed superiority to any one, which was claimed by all of them. The principal reasons for this are: The large number of repairs and consequently the many machines to be kept in reserve, which make the first cost of the plant too large to be practical in enterprises where time is only secondary in importance to economy. [At the Mont Cenis, one machine made only 30 feet of holes and then had to be repaired; at the Gotthard tunnel from 58 to 97 machines required repair monthly; at the Arlberg tunnel 330 feet of holes were made before a machine had to be repaired. At the Sutro tunnel it cost per month \$257.60 for repairs to keep 4 drills at work.] The useful effect of the motive power, which works upon the drill by a blow, thereby pulverizing it, is only very small, (not more than 20-23 per cent.) [An interesting article translated from the German and republished in Van Nostrand's magazine of September, 1877, page 268-274, Prof. Vick says: "If we use blows for shaping or dividing substances, a greater expenditure or waste of labor is neces-

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

Milling Gold Ores.

EDITORS PRESS:—In your annual number there was a letter from Mr. Drake, of the Patterson mine in Tuolumne county, in regard to the loss of gold by wet crushing and amalgamating on copper plates. He quotes numerous authorities to prove that the loss is all the way from thirty to sixty per cent. of the gold in the ore. Now, while there is undoubtedly great room for improvement in the working of gold ores, and the discussion of this question by practical mill men is of the greatest importance, still let us start fair and not from any false base of operations. In my opinion, and it is also the opinion of many practical amalgamators, with whom I have discussed the question, the loss of free gold is greatly exaggerated by so-called experts, and by collectors of statistics in relation to gold workings. The distinction between the free gold contained in the ore and that intimately combined with the sulphurets, whether chemically or mechanically, is not distinctly made in many instances. The sulphurets can be saved by means of shaking tables, as Mr. Drake acknowledges. Now, in most of the statistics from which he quotes, I believe, no account has been taken of the sulphurets in the absence of cheap methods for working and saving them; but the difference between the gold found in the ore by fire assay, and that obtained by mill process has been charged to the account of gold floating off "down stream."

This is manifestly unjust to the mill process by amalgamation on plates; and when to this is added the gold, unnecessarily lost by incompetent amalgamators and mill men, and by experiments of tyros, who, with no practical experience, attempt to revolutionize gold saving, another large item is added to the account. When Mr. Drake quotes "Fossett's Colorado," I can assure him that if many of the facts were gathered from such examples, as for instance, Judge, now Senator, Bowen's mill and mine in San Juan, where with seventeen inches drop, coarse screens and low speed, probably half his gold went down the gulch, a big percentage can be taken from the figures obtained in summing up. This last instance is, probably, but one of many. When Judge Bowen was told, on the spot, by an Amador county amalgamator, that he was losing gold unnecessarily, he replied: "I know it, but I am making \$700 a day, and that is good enough for me." Can there be a doubt, but that all that gold, thrown away, was charged to the account of the "defective mill process?" Again mining men, for obvious reasons, are inclined to exaggerate the value of ore; not from any inclination to deceive any one, but from the natural disposition all people have, of putting "their best foot forward," where their interests are at stake. What is more natural or easier to charge the deficiency in results to that same "mill process," and to say that the gold has floated off down stream. No such loss of gold as is claimed by Mr. Drake, under the authority of the various Professors mentioned in his letter, is acknowledged to take place by the best practical amalgamators and mill men, with whom I have spoken. Probably, on account of pride in their profession, they have bias on the other side, still they hold their work open to investigation, and I believe that despite the statistics, at least a "Scotch verdict" of "not proven," should be entered up against them. The temptation to continue writing on this subject and others allied to it, as well as on some other points raised by Mr. Drake, is enticing; but it is some time since his letter was published, and the ground may have been covered by others much more competent than myself. His letter was of great interest to me, and, I believe with him, that open discussion of these questions, by men engaged practically in milling, is the surest method of advancement.

W. S. DUVAL, M. E.
Angels, Calaveras Co. Cal.

SALT LAKE BUYING IDAHO ORES.—The Wood River Times says: The Times is informed, on reliable authority, that the Germania Company, whose works are located about six miles south of Salt Lake City, will soon enter the field on Wood River, with the determination to buy all kinds, grades and qualities of ores offered for sale. This will secure another outlet and market for our ores scarcely second to Omaha. The Germania Company is a joint stock concern, which is owned by Western men exclusively. Its plant, which is almost new and of the most superior workmanship, includes a sampling mill, three smelting furnaces, a refinery and a white lead, paint, sheet lead and lead pipe manufactory. This plant must have cost all of \$300,000. Besides this, the value of its ore, bullion, and other products on hand and in transit aggregates from \$700,000 to \$1,000,000, and its credit is A 1. It is therefore as powerful a combination as could be desired here. The Germania works have been in operation for some years, but it is only recently that the profits of the institution have been sufficiently encouraging to justify it in engaging in active competition with the smelting world. During the past year it purchased a

notable quantity of Wood River ores, and it has done so well on these that the management have determined no longer to restrict their purchases to our lower grade, light lead ores, but to buy all the ores offered. It is evident that the Germania Company have a special rate from the railway company; as at regular rates, to-wit: three and one-half cents to Ogden, they could not buy our ores at all. But whether they have or have not a special rate is immaterial to us. All that really concerns us is the fact that Salt Lake (or at least the Germania works) can still buy our ores, and will do so. Unless we are much mistaken, this announcement will have the effect of slightly improving the prices paid for our ores heretofore. But time will tell, as to this.

Manufacture of Soda from Sea Salt.

The municipality of Issoudun, having resolved to erect a monument to Nicholas Leblanc, the pioneer in the artificial soda industry, M. Dumas gave an eloquent address to the French Academy upon the importance and vicissitudes of that branch of manufacture. A hundred years ago the French government consulted the Academy as to the best means of replacing the soda supply, for which they had been dependent upon Spain, and a prize of 12,000 francs was offered to the inventor of a successful process for extracting the alkali from sea salt. When Leblanc had fulfilled the conditions of the prize the Academy had ceased to exist. The inventor was obliged to renounce his rights, to close his factory and to live in the extreme of poverty, until finally he committed suicide. Many persons would be surprised at the information that the two greatest economical novelties of the century are the steam engine and artificial soda; the two most fertile inventors, Watt and Leblanc. While the engines created by the former act with a great noise in all our factories, carry the trains of travelers and merchandise over the iron roads with which the continents are furrowed, or guide ships of commerce and war over the waves of the sea, the soda products penetrate into all our workshops and dwellings, as indispensable elements or auxiliary agents of labor, and as direct or indirect objects of consumption. If we were asked which of the two inventors, Watt or Leblanc, has most greatly increased the welfare of our race, we might hesitate for an answer. All the ameliorations in the mechanic arts spring, it is true, from the use of the steam engine; but all of the benefits which pertain to the chemical industries have found their point of departure in the extraction of soda from sea salt. The first result of the soda factories placed at the disposal of the soap makers, the glass manufacturers, the bleachers and the paper makers, the alkali of which they have need, and also offered to all industries sulphuric and chlorhydric acid, in unlimited quantities and at prices fabulously reduced. The second result was the introduction of chloride of lime for the rapid bleaching of vegetable tissues, in place of the slow action of solar light and damp air upon pieces of linen spread upon the grass. The four agents—a powerful alkali, two energetic acids, a bleaching powder which nothing has supplanted—gave an unprecedented range to chemical industries, and raised the question whether it was wise to leave the fabrics dependent upon the sulphur of Sicily, which might, at any moment, be enormously advanced in price; and iron pyrites, which had previously been almost worthless, was largely employed in the manufacture of sulphuric acid. The growth and competition of large soda factories reduced the price until it became necessary to look for new sources of profit, which were found, for awhile, in the manufacture and sale of chloride of lime. The leaching of the crude soda to extract the carbonate left residues, which contained all the sulphur of the sulphuric acid united to the lime. This refuse incommenced the whole neighborhood, infecting the water courses and the shores of the sea itself. These annoyances were removed by the invention of a process for regenerating the soda which was left from the leachings. The manufacture of chlorine and chloride of lime consumed peroxide of manganese, and produced chloride of manganese in great quantities. The peroxide is a natural product of limited supply; to increase its consumption is to raise its price. The chloride destroys vegetation and infects the streams; a considerable daily production of it creates a thousand difficulties. They have been obviated by a process for regenerating the peroxide, and thus getting rid of the chloride. Meanwhile, the competition continuing, and the price of soda steadily falling in proportion as the cost of manufacture diminished, help was sought—not in new economies, but in the treatment of ores capable of furnishing remunerative merchantable products. Hence the iron pyrites were replaced by copper pyrites which were accompanied by precious metals, and the profit was sought in the silver or gold which could be extracted from their cinders. This strife is now to be renewed with a rival process founded upon the decomposition of salt by ammonia, in presence of an excess of carbonic acid. Whatever may be the result of the contest, it is fortunate that modern chemistry has had the various practical schools of industry which have resulted from Leblanc's process, and which have exercised an incalculable influence upon all civilized countries.

The Mother Lode at Cœur d'Alene.

The mother lode is about two miles above Murrayville, in the bed of Pritchard creek. Messrs. Lewis, Harris & King, who own a two-thirds interest in the claim, uncovered the finest of the quartz for our inspection one day last week. The ledge is about four feet high, and is from three to seven feet wide. It has only been traced a few yards, and apparently plunges into the mountains on either side of the creek. It shelves downward as it enters the mountain. A table of rock, perhaps six or eight feet square, is literally spotted with large blotches of free gold. It is the prettiest sight we ever laid eyes upon, and a slab from the face of the quartz would command a fabulous sum for a shop-window or cabinet. Mr. Harris first discovered the rock containing free gold. He was prospecting for placers, and accidentally came upon it in the bed of the stream. Nothing is known of the extent of the quartz. The discovery was made October 19th, and the snow came in then to interfere with the running of the lines when the location was being made. The owners have never touched the claim, and will not allow any one else to interfere with it. The quartz, filled with gold, lies exactly to-day as it did when first found. The discoverers own a fractional placer claim, including the ledge, and have taken out ten dollars to the pan in the creek below. They offer to sell for \$30,000, but will take no less sum, and will not listen to any offers for bonding. If the quartz is detached, or only a pocket, they will still realize a snug little sum from the gold that is in sight. All the quartz in the ledge assays well, even that which shows no trace of free gold assaying as high as \$227.38 in gold and \$32.32 in silver. We saw the returns from this assay, which were the lowest ever made. If the sale is not effected within a short time, the owners will begin work. They are elderly men, old miners, and feel as if this was to be their last stake. They have lived in a cabin in sight of their treasure, throughout the long, dreary winter. Loose slate rock is scattered over the quartz, and a thousand men might visit the spot without discovering the rich quartz. When they wish to exhibit the gold, they remove the loose rock with a shovel, and splash water over the rock and wash the dirt away. The sight is a dazzling one, and no words can give an adequate description of it. So many men are applying daily to see the gold that the owners have been compelled to refuse hundreds. It would keep one man constantly employed if it were on public exhibition. Indeed, it is strange that the old miners do not charge a dollar for the privilege of seeing the ledge. They would coin money by adopting such a suggestion. The ledge enters a mammoth cliff of slate, and is widest at the place where it enters the cliff.—Nugget.

Stampedes.

The danger of stampedes is one which all new settlers in mining camps must figure on. Let's figure. Three thousand men are in the mining district. They have come early, purposely, in order to get chances for investment. They knew when they came that they were a month or two ahead of schedule time—that no mines could be opened, and few prospected until the snow began to melt. Suppose twenty-five hundred of these men got broke, and the supposition is not unlikely, and rush back home. That is called a stampede. Men are crazier than cattle or horses. They are about like sheep. If one jumps over a fence, or into a ditch, the crowd follows. If a few men give a camp a black eye and leave, hundreds will follow. Leadville had a stampede, in her palmy days, and it lasted some months. The Cœur d'Alene had a stampede on a small scale last summer. Suppose another should occur. It isn't probable, but we are figuring on the possibility. Suppose the towns over built, property acquires fictitious values, and the boom should collapse in a stampede. It would take grit and nerve to remain. Like a flock of sheep or frightened cattle we would all catch the infection and feel like running away. But some would remain. Some are hobbled with claims and town property, and can't run. Some are tethered to business and must stay. A few are long-headed enough to stay anyway. Suppose we stay. Desirable property will come down to a reasonable figure. A little capital will secure something like its value. We will reap where the stampede has sown. Pretty soon, it may be months, it may not be six weeks, the tide will again set this way. Thousands will come instead of the hundreds who are now here, just as hundreds have now come instead of the tens who were here last summer. Then comes our harvest. The few who remained here during the long, weary winter are all doing well. They have mining property and town lots. Those who remain during future stampedes will make fortunes. We write this with no belief in a present stampede. There is too much gold in sight, and too many men doing well, for any serious rush to the railroad to occur speedily. But, in all likelihood, there will be partial stampedes before the mines are much older. Many men who came here with a thousand dollars one month ago are getting hard up; some who came with five hundred dollars are broke, and few that came with a hundred have anything left, unless they are willing to work. There is plenty of work, but stampedeers are

not looking for that kind of a layout. After figuring carefully, we don't see that a stampede or two would do any great harm. We would hardly miss those who are dead broke, before their places will be taken by men of means, by prospectors and laborers. These latter classes are coming in so rapidly that there cannot be a stampede. The incoming population must constantly outnumber the outgoing. Still, if it would be a genuine benefit to the camp to change off its poorer occupants for a better class, let us side with the croakers until the change is effected. Let us one and all cry *Viva la Stampede!* But we won't stampede. We will stay.—Cœur d'Alene Nugget.

The Lead Market.

The Salt Lake Chronicle says if the tariff tinkers will let lead alone the prospect for fair prices for that article the coming season is good. The Morrison bill now before Congress for defeat, we trust, proposes to reduce the tax on lead 15 per cent. This reduction, with the price of lead steady at \$4.25 in New York, would probably enable foreign holders of lead to flood our market. It is to be hoped that if any reductions are to be made on imported articles, lead will remain untouched. The lead interests, or in a larger sense, the lead-silver industry, will suffer materially should the tax on lead be reduced. Already at present prices of lead there are large deposits of low grade silver-lead ore which cannot be handled with profit. Reduce the tax, and mines now barely paying will be closed. Aside from the tariff matter, the prospect of immediate and permanent advance to a paying point in the price of lead is promising. Owing to various reasons, prominent among which is the unusual fall of snow in the mountains all through the mining districts, the outcome from mine and smelter will be less for the next few months than usual. This is but temporary, of course. There are permanent causes at work. As depth is reached on our silver-lead producing mines, it is generally true that the percentage of lead decreases. In the meantime, with the growing trade and activity of business in all departments, the general demand for lead, as for all the useful metals, is continually increasing. The promise of supply is not likely in the future to keep pace with the demand. And this is true of gold and silver as of lead.

The mining districts of the world are being largely explored. The maximum of production seems already to have been reached, and we are on the descending grade. Improved processes of reduction, larger combinations of capital at less cost of usury, with improved facilities for transportation, will lessen the cost and relatively increase the profits of mining in the future. Of all industrial pursuits, mining is king; that is, its products are absolutely necessary for the uses of trade; they are less liable to fluctuation in price and appreciate in value as other commodities diminish. In times of great financial depression and panic the production of gold and silver, with attendant lead, is the only business that holds its own as master of the situation.

Let the man who holds a vein of lead with small value of silver therein perfect his title to the same and "wait for the wagon," for the time will soon come when such veins and deposits will be worked to profitable advantage.

QUARTZ AND DRIFT MINES.—The Mayor of Marysville on reading his inaugural recently before the Common Council of that town, said: As to the quartz system of mining, the assertion that we are antagonistic to its continuance is made only by those whose personal interest in the hydraulic mines leads them to desire the support of the quartz interest. This assertion is not worthy of refutation. Regarding the drift system of mining, where only the pay gravel is removed, we are assured from the statistics in our possession that the debris coming from their operations is so inconsiderable in amount as to do no appreciable injury, and we cannot doubt if those engaged in drift mining use all effort to make as little deposit in the rivers as is practicable, we shall have no occasion to complain. No system of mining would be tolerated that should increase the filling of her river channels. It is the belief that the drift system of mining can be so conducted as not to injure the valley that leads us to disclaim any opposition to it. If drift mining is carried on in a manner not materially injurious to the valley—that is, not detrimental to the carrying capacity of our rivers—it will never be disturbed. We are not contending for clear water, but the rivers must be brought to such a condition that not only further filling of their channels shall cease, but from this time on their channels shall constantly scour out and deepen. Companies not now resting under an injunction, that are furnishing water to quartz, drift and hydraulic mines, as well as for domestic purposes and irrigation—if they desire to avoid litigation and an injunction that shall tie up their property, have only to cease furnishing water to those engaged in hydraulic and sluice mining, and they will not be proceeded against. This great public nuisance has been occasioned solely by hydraulic mining, and we must never rest until all mines worked by the hydraulic system, or any other method of mining, whatever its technical name, that slices the whole face of a bank into the river, shall have ceased their operations.

MECHANICAL PROGRESS.

An Unusual Grouping of Steel Rails.

The following curious fact is noted by the *Industrial World*: "At a somewhat important junction in one of the smaller Western cities there are to be seen, in the track of the branch line, within the distance of one-third of a mile, no less than ten different brands of steel rails, all in current use and rather heavily traveled upon. These ten names include three English works, one French, one Eastern work in this country, three which may be called central, and two Western works. These rails appear to have been gathered from time to time out of the remnants of larger shipments made to central points on other parts of the main road of which this branch formed a part, or to have been picked up occasionally as left along the track when changes had been made from iron to steel. All were in excellent condition, and for obvious reasons no pretense could be made of a comparison between them. A rather interesting illustration was thus afforded of the wide range in the sources of supply of such construction materials, and of the difficulty of controlling the inevitable variations in the quality of the product when received from so many different hands and made up of such various and dissimilar materials. It is a little difficult to believe that these rails, from so many makers' hands, could have been any better suited to their purpose, or could have been absolutely guaranteed as of the best absolute quality, if they had been made under any arbitrary quality whatever, and not made (as they undoubtedly were, whether good, bad or indifferent) with a reasonable sense of responsibility on the part of the maker, as measured in part by his own study of the general range of tests required, and of the raw materials at his command."

STRENGTH OF PORTLAND CEMENT.—The Portland cement, as it comes from the factory, is composed of an almost impalpable powder, mixed with coarser grains which have but little adhesive quality. Mann's experiments have shown that in a trial of seven days the portions which pass through a No. 176 sieve (31,000 meshes per square inch) exhibit five times the adhesive strength of those which pass through a No. 103 sieve (10,600 meshes per square inch). The necessity of fine grinding is therefore obvious. In ordinary cement 45.6 per cent is stopped by the No. 176 sieve, which is the finest that is made. The force of cohesion is much greater than that of adhesion, varying from threefold to tenfold. The adhesive force upon different substances, such as stone, brick, slate, marble, glass, etc., varies greatly. The degree of surface polish has less effect than one would think. According to these experiments, the best test of Portland cement is its adhesive power. The No. 176 sieve ought not to stop more than 45 per cent of the cement; the part which traverses the sieve should have an adhesive force of 95 pounds, and the unsifted cement of 75 pounds per square inch. —*Chron. Industr.*

BRONZING IRON.—Iron articles are easily coppered or brassed by dipping in copper solutions, or else coppered or brassed by the galvanic method; these coatings also scale off after a short time, especially if the iron surface was not thoroughly cleaned, when exposed to the influence of moist air. By the following process it is easy to provide iron articles with a handsome bronze-colored protide coating; it resists the influence of humidity pretty well, and besides this, the operator has it in his power to produce any desired bronze color in a simple manner:—The cleansed and scoured articles are exposed to the vapors of a heated mixture of concentrated hydrochloric and nitric acids (1 and 1) for from two to five minutes; and, then, without unnecessarily touching them, heated to a temperature of 300° to 350°. The heating is continued until the bronze color becomes visible upon the articles. After they have been cooled, they are rubbed over with petroleum jelly, and again heated until the jelly begins to decompose. After cooling, the article is anew rubbed over with petroleum jelly. If now the vapors from a mixture of concentrated hydrochloric and nitric acids are permitted to operate upon the iron article, light red-brown tones are obtained. However, if acetic acid is mixed to the mentioned two acids, and the vapors permitted to operate upon the iron, oxide coatings are obtained, possessing a handsome bronze-yellow color. All gradations of colors from dark red-brown to light red-brown, or from light bronze-yellow, to dark brown yellow, are produced by varying the mixtures of the acids. —*Dinglers Journal.*

TESTING MACHINES.—The prominence which has lately been given to the discussion of improved testing machines, both at the meetings of the different engineering societies of the country and in the scientific press, naturally brings to mind, by way of contrast, the fearfully and wonderfully made contrivances for testing one used to meet with in iron works and foundries in former years. The improvement in testing machines has, however, merely kept pace with the clearer perception of the various physical qualities of metal to which makers and users of iron and steel have come, and so the worst that can be said of these primitive fixtures is that, while they never did any good, they never did much harm, as their use, from the very crude-

ness and evident inaccuracy of the apparatus, was rather short-lived. Good testing machines are now manufactured at prices which bring them within the reach of most works, and with the better appreciation of their value to the iron-worker has also come a clear understanding of the fact that a testing machine must, above all, give correct results to be of any use whatever. —*Iron Age.*

WATER IN BOILERS.—The danger of allowing water to assume the spheroidal condition in steam boilers is generally recognized; and M. Melsens has investigated the causes which conduce to this state. He has found that when the shell of a boiler is roughened with many points, water boils at the same temperature as that which in a perfectly smooth boiler will produce the spheroidal condition. The demonstration of this fact has been shown by the following arrangement: A dish representing the bottom of a boiler is divided into two equal parts, one of which is made perfectly smooth, while the other is covered with little pointed metallic cones, soldered to the plate. The dish is raised to a uniformly high temperature by a gas furnace, and then a quantity of water is poured simultaneously into both compartments, rising high enough to just cover the points of the cones. In the smooth compartment the water will pass into the spheroidal condition and not enter into ebullition; in the other, the ebullition will be lively so soon as the water covers the points of the cones. The same phenomenon occurs when the water has, by long boiling, been previously purged of its contained air. It remains to be proved whether this experimental fact can be utilized in the construction of boilers, in order to suppress or diminish the disasters arising from overheating. —*Scientific American.*

SELF-PRESERVING IRON.—To the chemist it has long been a wonder that the oxides, which in large mills amount to no insignificant sum thrown away, had not been utilized for some purpose in the arts or manufactures, when it was a notorious fact that iron in the form of rust contains all the primary requisites as an effectual preventive of the recurrence of rust, the great question being some manner of application, that would act the same in all climates and situations. Circulars and samples lately received from England seem to indicate that this question has been solved, for a factory for the manufacture of rust paint has been established at Bownessfield, a small borough near the famous steel works of Elton. This firm obtain their scales from these works and other rolling mills adjacent, as it passes from the machines, and by processes known to themselves is manufactured into paint for iron. Thus we may have steel structures painted with steel and apparently this steel covering will last forever. The scales of rust may be reduced by crushing to a powder possessing not a particle more grit than wheat flour, after which it is readily mixed with oil and the shade of color desired is made the same as other paints. It is stated that a ship's bottom was painted with this new discovery of an old product, and made the voyage from London to India and return without even the slightest indication of barnacles or grasses.

A FINE FINISH FOR STEEL.—A fine lusterless surface on tempered steel can be procured by either of the following operations: After the steel article has been tempered it should be rubbed on a smooth iron surface with some pulverized oil-stone, until it is perfectly smooth and even, then laid upon a sheet of white paper and rubbed back and forth until it acquires a fine dead finish. Any screw holes or depression in the steel must be cleaned beforehand with a piece of wood and oil-stone. This delicate lusterless surface is quite sensitive, and should be rinsed with pure soft water only. A more durable finish is obtained by smoking the steel surface with an iron polisher and some powdered oil-stone, carefully washing and rinsing. Then mix, in a small vessel, some fresh oil and powdered oil-stone, dip into this mixture the end of a piece of elder-pitch and finish the steel surface with a gentle pressure, cutting off the end of the pitch as it commences to become soiled. In conclusion, it should be thoroughly cleaned in soft water, when the article will be found to have a fine lusterless finish. —*The Amateur Mechanic.*

FINE WIRE.—We recently alluded to some very fine drawn platinum wire, fine enough for cross hairs of telescopes, but too weak to handle. The *Scientific American*, in reference to the same, says that Dr. Wollaston published, as long ago as 1813, an account of his making a wire only one-eighteenth thousandth of an inch in diameter. The size ordinarily use for field transits is platinum wire of 0.003 inch, covered with silver to 0.1 inch; this drawn to 0.003 inch will leave the platinum, when the silver is dissolved off, to be 0.00009. This wire will sustain a weight of four grains or a ball of wax the size of a pea.

To prevent the cracking of the glass tubes which are connected with steam boilers to show the height of the water within, and which is of a more or less frequent occurrence, as the tube is of a high temperature inside, and a cold current can strike them from the outside, the *Industrie Blatter* recommends the use of two glass tubes, one within the other. The air which is confined between the two serves as a protection to the inner tube against outside cold and the outer one against the high temperature of the inner one. Both tubes are packed in brass couplings, and form one single instrument.

SCIENTIFIC PROGRESS.

The Theory of Magnetism.

At a recent meeting of the Royal Institution, Professor D. E. Hughes gave a lecture on "The Theory of Magnetism," illustrated by experiments. The mechanical theory of magnetism may be deemed to be the proper style and title of that brought forward by the lecturer. The phenomena of magnetism he explains by a simple rotation of the molecules of iron, as well as of all metals; nay, more, of all matter—solid, liquid, gaseous, or ether. All matter according to his views, has inherent magnetic power, varying in degree in molecules of different nature, but not to any great extent.

The lecturer demonstrated each portion of his theory by experiment, so that the effects were visible to the audience. The striking effects of vibration, torsion, or mechanical strain upon the destruction or creation of manifest magnetism he showed in a variety of ways, the soft iron obeying the slightest mechanical tremor; while hard iron or steel resisted the most violent treatment. The molecules of the same bar behaved with extreme freedom, as in the instance of soft iron, but when a slight strain was put upon them, as when slightly bent, like an archer's bow, the bar became as rigid as steel, and mechanical action had no longer any effect.

A detailed account was given of the lecturer's researches upon the atmosphere, in the course of which he has discovered that it has a saturating point, like iron, and that it is just like iron itself. This was illustrated by striking experiments upon the magnetism of the atmosphere as compared with that of iron, and with the effects of vibrations in allowing freedom of motion to magnetic conduction in iron, by means of which a magnetic pole was pushed forward to four times its previous distance. Heat and electricity produced like effects, when Professor Hughes drew the conclusion that these three forces, each allowing molecular freedom from frictional resistance is lessened, must have a like origin, and that electrical currents can be fairly classed with heat as a mode of motion. When a bar of soft iron is strongly magnetized, as in the instance of an electro-magnet, it returns, like a spring, to a neutral state upon the cessation of the inducing force.

This well known fact has long remained a mystery. All theories of magnetism up to the present time supposed that the molecules became, on the removal of the induced current, mixed or heterogeneous. Professor Hughes believes he has made a great discovery in having solved this problem, leaving no mystery any longer, as the demonstration which he will soon bring before the Royal Society will reduce the matter within the domain of absolute fact. He proved his case before his audience at the Royal Institution in a less formal way, but quite as effectually, rendering a bar of iron sensibly neutral or polarized at will by simply turning it upside down. The mechanical inertia of the molecules was demonstrated by magnetizing a bar, that heat is a mode of motion, and that the molecules of the most solid bar of iron can move in a certain space with comparative freedom, the oscillations being greatly increased with every rise in temperature. If, as already well-known, the molecules can move in all planes, then there could be no valid objection to the idea of their rotation, in fact, they were known to rotate in the act of crystallization. Thus, according to Professor Hughes, magnetism is an endowment of every atom of matter. —*Scientific American.*

CONCERNING METEORS.—In the course of a series of instructive lectures on astronomy, recently delivered in New York by Prof. C. A. Young, of Princeton, that gentleman spoke of meteoric bodies as follows: Meteoric particles are striking the earth at all times. Some astronomers estimate that as many as 10,000,000 particles strike the earth each day, while the lowest estimate puts the number at 7,500,000 per day. Many more of these particles strike the earth in the morning than at night, and frequently observing persons in their morning walks can plainly see evidences of the meteoric showers. These meteoric particles seem to be circulating in space, and the earth as it moves in its orbit, strikes against them. Some of the meteoric showers are very copious and very bright. One writer has likened a meteoric shower that he saw to a snow storm, the flakes being of fire instead of congealed vapor. The majority of the meteors that strike the earth are stone, and not iron, as is commonly supposed. Some, however, are of pure iron. Out of the 500 or 600 meteoric stones that have been found on the earth and preserved, not more than ten were iron. Astronomical observers have detected, by means of the spectroscopic, sodium, magnesium and sometimes iron in these bright shooting stars. One consequence of this constant falling of meteoric particles, is that the earth is growing larger; but the lecturer said that there was no immediate danger of any radical change taking place in the surface of this sphere, for at the present rate of meteoric fall, it would take 500,000,000 years for the earth to gain one inch of surface. Meteors are known to come in periodical showers, probably the most remarkable being the shower that occurs about the 11th or 12th of November. It appears that meteors follow in the track of comets. They are related to comets in some way or another, but exactly how the lecturer was not prepared to say. Some

scientists thought that the meteors were the debris or cast-off particles of comets, while others thought that perhaps the comets were simply aggregations of meteoric particles, and the falling stars were the particles that did not get into the aggregations. It is certain, at any rate, that flocks of meteors follow the various comets at a few millions of miles behind.

THE ZODIACAL LIGHT.—The cause of the luminous phenomenon known as the zodiacal light has long been the subject of speculation, and numerous hypotheses have been suggested to account for it. A correspondent of *Cosmos les Mondes* regards the entire phenomenon as one of the reflection of light. What we observe is nothing but the reflection of that part of the earth which is illuminated shortly before the sun rises and after it sets. In order to understand this we must assume that the earth is surrounded for a certain distance by a comparatively dense envelope of gas, beyond which the latter exists in a state of great attenuation. We therefore have two media of different density which influence the rays of light in the well known way, refracting them up to a certain limiting angle of incidence, beyond which total reflection takes place. If we imagine the sun a little below the horizon, a part of the earth directly in front of us will reflect the rays of the sun at a very obtuse angle; these rays, meeting the boundary of the media at a very obtuse angle, will be totally reflected, and it is these totally reflected rays which we see. This explains the appearance of the light in the shape of a cone whose line is always inclined in the direction of the ecliptic, and whose base is toward the sun; it also accounts for the fact that the changes observed in its appearance follow a reverse order in the evening from that in the morning. The reason why the cone is longer in the evening than in the morning is that the layer of dense atmosphere is expanded by reason of its exposure to the sun's radiation through the entire day, whereas in the morning the reverse is the case.

VELOCITIES.—An interesting table of velocities has been drawn up by Mr. James Jackson, the librarian of the Paris Geographical Society. He begins, says the *Photo News*, with the velocity of a man walking two miles and a half an hour, and after alluding to the respective velocities of an ordinary wind, of a race horse, of an express train, of a carrier pigeon, of a hurricane, of sound in air and water, he brings us at last to the velocity of heavenly bodies, of electricity, and finally of light. But Mr. Jackson has left out one important velocity, which has only been recently computed, and which is of singular interest, since it represents the only earthly agent known to man with a velocity quicker than sound in water, although naturally less quick than electricity and light; we mean the detonation of the photographer's old friend, gun cotton. Abel and Noble have computed that a train of gun cotton, fired with a fulminate fuse, will transmit the detonating action at a speed of from 17,000 to 19,000 feet per second. In other words detonation travels at the rate of 200 miles a minute, while next in order comes electricity, traveling through a submarine wire at a speed of some 12,000,000 feet per second.

PRACTICAL SCIENCE.—An instance of the practical application of science to every-day life is well shown in the building of the capitol building of Dakota, at Bismarck, by the aid of electric light. This building, costing a quarter of a million of dollars, consists of three stories, basement and sub-basement, measuring a hundred and fifty-five feet by ninety-two feet, and contains over four million bricks, with trimmings of Joliet stone, and has been erected in the midst of winter. The corner-stone was laid Sept. 5, 1883; and on the 10th of January, 1884, a few days more than four months later, a photograph shows the building to lack only the projection of one side and the upper part of the tower. This result was accomplished by the employment of electric light, which half the time replaced the sun, enabling double gangs of men to work day and night. The frozen sand was thawed by a red-hot cylinder, and the mortar, made with boiling water and hot lime, had its moisture absorbed by the dry bricks before it had time to freeze. Although taller, the building is an almost exact duplicate of the new capitol of Minnesota.

CANNED FRUIT.—Mr. Winter Blyth has recently been employed to analyze imported canned fruits (apricots, tomatoes, etc.) in order to ascertain the amount of contamination by metal in them. In twenty-three samples the amounts found, calculated as stannous hydrate, ranged from 1.9 grains to 14.3 grains per pound, the mean amount being 5.2 grains. The juice and fruit in some instances had a metallic taste. Several of the tins showed signs of corrosion. The *Journal of the Society of Arts* says: The little that is known of the action of stannous hydrate may be summed up in a few lines. Doses of about 174 gram per kilogram of body-weight cause, in guinea pigs, death with signs of intestinal irritation; but with doses smaller than 17 to 2 gram the effects are uncertain, and the animals generally recover. Hence, supposing a man to be affected in the same proportion, he would have to take from three to four drams, or consume at a meal ten pounds of the most contaminant of Mr. Winter Blyth's tinned fruits. But it is not a question of immediate deadliness; it is rather one for inquiry as to the action of small repeated doses continued for a long time.

Passing Events.

Among the mining items of note is the discovery of new mines northeast of the Pikes Peak or Yambelle district, in Montana, and not far distant. The mines are placers; we refer to the subject in our Mining Summary. The Spicer district, some seventeen miles from Quijotoa, Arizona, is also now attracting attention. A great excitement was raised last week in Colorado about new gold fields at Pisgah. A regular stampede set in from Denver and elsewhere. It has been found already, however, that the whole thing is a fraud, a job put up by somebody.

The Cœur d'Alene rush still continues, but many contradictory reports come from the new mines. Of late many letters written from there give the mines "a black eye." A few weeks more will tell the tale, however.

A BIG PAYING MINE.—The Bald Mountain Extension Co., in Sierra county, recently made the largest clean-up ever had. It was 217 ounces, \$4,036.20, the gravel averaging \$3 per car-load. During the past three weeks they have taken out 540 ounces, \$10,044. A dividend of at least three cents a share will be declared for this month on the Extension stock. The yield of the mine for the first three months of this year was \$25,924.84. The pay roll during that time was \$11,555.75. Total proceeds gold dust since pay gravel was first struck in the lead was \$115,610.44. The main tunnel is now over 650 feet in the lava flow, beyond which will undoubtedly be found the extension of the pay channel. Total length of main tunnel over a mile. Sixty-five men are now constantly employed. Total amount of assessments levied to develop this mining property, \$57,390.

Progress of Mining.

It was not very many years ago that the precious mining industry of the United States was confined to a comparatively small area. It was in California and Nevada that the principal work was done, and few of the big mining magnates cared to have anything to do with any of the mines which had been found in other States or Territories. In fact there were not any big mining magnates to speak of; but such as they were, these men preferred to deal with such mines as could be readily managed from San Francisco as a center. Gradually the California mines came to be neglected by these men, and their whole attention was then turned to the Comstock lode in Nevada, where the most extensive mining was carried on.

As one after another of the famous mines of that lode showed up a rich spot the attention of the mining world was still more concentrated in that locality, and men found it exceedingly difficult to get any capitalist to look at anything anywhere else. By and by the famous bonanzas were opened, and then there was no chance for any other region.

With these discoveries came the day of extravagant ideas, expensive machinery, immense outlays and sudden and magnificent fortunes. During this time the mining regions of the rest of the country languished for want of capital or other encouragement. To California indeed this, though at the time considered very unfortunate, was a good thing. The miners here learned to rely more on themselves and became much more economical in their conduct of mining operations. Instead of there being many "one mine camps" each camp began to develop its small mines. The result has been that the State of California has been able to maintain steadily the first place as a gold producer and the second place as a gold and silver producer, notwithstanding the lack of encouragement from capital. Each year there is a great stir from some of the other States and Territories about what they are going to do, and each year California turns up ahead of all but Colorado, which a few years ago wrested the first place from Nevada.

But while the wonderful results were being accomplished on the Comstock the miners elsewhere were hiding their time. The newer regions of the United States were gradually receiving additions to their population and the miners were roaming over the hills and mountains and hunting up new locations for themselves.

The discovery of the mining regions of Leadville at Colorado perhaps did more to attract the attention of the people west of the mountains to precious metal mining than any other thing—even the bonanzas of the Comstock. The mines were nearer them and the rich ore developed yielded so much that it attracted the thoughts of many all over the country.

The possibility of gathering wealth from this business having been impressed upon the people East, who had only looked upon mining as a sort of adventure or precarious occupation, the mining industry became a more legitimate thing in their eyes. Thousands of men who had not before thought of the matter, suddenly became interested, and the result was an influx of capital to the mining regions and a large accession to the number of prospectors in the country.

The building of railroads in the southern and northern part of the United States has had the effect of opening up regions before left to the Indians almost exclusively. With means of transportation at command, and some protection for life and property assured, these regions referred to have rapidly settled up with a community progressive and energetic in its nature, and both ready and able to found new States, and wrest from the earth and soil the latent riches they possess.

In Arizona the Tombstone mines have become famous for their yield of precious metals, and the Bisbee mines for their wealth of copper. But half a hundred other districts, not so noted, but with great possibilities, have been discovered and developed. The whole territory seems to be prolific of mineral, and it is only now in its infancy of mining development. New Mexico, while it has been somewhat unfortunate in being "boomed" before it was quite ready, has shown up some good mines, and has hardly begun to make the showing it can by and by.

The great Black Hills excitement also added its influence in bringing about the revival of in-

terest in mining. The mining region of Dakota, though not so wide in area as that of other States and Territories, has proved a profitable one. Some of the mines have proved exceedingly rich. To these mines, too, came a large number of people who had never before been connected with mining in any of its branches.

But perhaps the most remarkable strides which have been taken of late years have been made in Montana and Idaho. The mines of the Wood River region, in the latter Territory, and those of Butte, in the former, have attracted large numbers of men to the North. The developments which have taken place have been very satisfactory, and the mining fields are widening. It is yet too soon to speak with any degree of certainty of the new placer regions of Idaho, which are the object of the present prevailing excitement. Utah is rather quietly making for herself a reputation for producing mines, and her bullion product is steadily and surely increasing. Some of the noted mines within her boundaries have done her more harm than good from the reputation achieved by their manipulators; and some earlier mistakes were disadvantageous. But now she has a few mines of wonderful richness, and a very wide available mineral region. With very little flourish of trumpets Utah is making developments and bullion shipments which are rapidly leading her name towards the top of the list for bullion production.

The progress of events show that gradually more and more attention is being directed by the American people to the rich mining fields of Mexico. Already some hundreds of mines within her borders are owned by companies formed of citizens of the United States. Individuals are investing there, too, and notwithstanding the drawbacks of lack of means of transportation and the dilatory habits of the people, great strides are being made. The introduction in the mines there of modern mining machinery and appliances, as well as American habits of industry and energy, will sooner or later work a complete revolution in mining matters. The country has for centuries been noted for the richness of its silver mines, and many of them have only been worked to moderate depth, and with crude appliances. With the increase of railroad facilities, the prospects of that country and its mines will be very greatly improved. In Oregon and Washington a certain amount of mining development is going on; but as compared with other regions, it attracts little attention. In the Southern States there are many mines also, but none which have a world-wide reputation for richness.

With this progress of mining, the progress of mechanics relating to the industry has kept in pace. There are foundries and machine shops all over the country that make machinery for use in mines. Naturally, California keeps in the lead in this branch, having had the longest experience. The mining appliances made at the foundries of San Francisco have a reputation all over the world for strength, durability and adaptation.

The mining industry is now so firmly established on a legitimate basis in the United States that all questions as to its being a business in which men can engage without being looked upon as speculators are idle. True, the taint of the stock market is somewhat too strongly fastened upon it, but the signs of the times and our present experiences show that this will be a constantly lessening evil.

Anthracite Mining Methods.

The pillar and breast system is the one by which almost all anthracite mines are worked, but the details of the system under different mining conditions vary so widely that a comparison of mine maps from different districts, or a hasty trip through collieries in different localities, gives the impression that the coal is mined by several systems having nothing in common, but a close inspection discloses the fact that they all have three identical features: 1st., the breasts or rooms, or working places, are all long and comparatively narrow; 2d., they are driven nearly parallel to each other, and 3d., they are separated by long, narrow pillars of coal, broken only by small openings for ventilation.

These features, common to all anthracite workings, are the identifying characteristics of the "pillar-and-breast," "pillar-and-room," "post-and-stall," "stoop-and-room," or "board-and-pillar" systems.

At present beds of from three and a half to four feet up to 60 or 70 feet are worked, and on dips varying from horizontal to vertical, and it is a somewhat remarkable fact that the same general system can be employed in mining the coal from a six-foot bed lying nearly horizontal, that is adopted in working a 50-foot bed standing nearly vertical; but the details of such working differ materially. The plans in use at present may be divided into two classes: 1st., workings on beds dipping from zero, or horizontal, to an angle of about 25 degrees; 2d., workings on beds dipping from 25 degrees to 90, or vertical. These two classes may be appropriately termed "flat working" and "pitching," or "steep workings."

Seventieth Birthday Reception.

On Friday evening last a very pleasant social event occurred at the residence of Mr. W. B. Ewer, of the firm of Dewey & Co., the occasion being the celebration of Mr. Ewer's 70th anniversary. About 125 of his friends came to present their congratulations. Appropriate remarks were made by Mr. Bacon, Rev. Henry A. Sawtelle, Dr. Cleveland and others. Dr. Blake presented Mr. Ewer with a handsome gold-headed cane from members of Ivy Chapter, Order of Eastern Star. A number of other presents were received from friends and business associates. Parlor theatricals, music and conversation enlivened the evening and a bounteous repast was served. The toilets of the ladies present were exceptionally fine, and the evening was heartily enjoyed by all so fortunate as to be present. The floral decorations and offerings were remarkably elegant. During the evening the following poem was presented by A. T. Dewey:

A Birthday Poem.

Respectfully dedicated to W. B. EWER, A. M., a pioneer veteran of the press of California; written on the occasion of his Seventieth Birthday.

Hail to "The Press," and to the band
That built its temples in our land!
To hands that toiled, to feet that sped,
And to the stalwart brains that led
Our pioneers through the maze
And fever-heat of early days!

Hail to the men who long have wrought
Their jewels from the mine of thought!
Who've sent, equipped and manned with might,
Crowned with the truth, and winged with light,
Their thoughts and inspirations grand,
Like armed warriors through the land!
Hail to the pioneer who came
With Printing Press to lead and tame
The fiery spirit of a band,
That revelled in the Golden Land!

The years have sped, matured and ripe,
Now stands our "Veteran King" of type;
The sun of time has sweetly shed
Its silvery halos round his head,
Yet in his soul there is a glow
That shone so buoyant long ago;
The same determined zeal that made
Him knightly master of his trade.

The suns of seventy years have set,
The golden spark is shining yet;
The placid current still flows on
Through fields whose prizes have been won—
With no discordant note to mar
The beauty of eternal law.

Though seventy years have come and gone,
The regal spirit still shines on—
For no unmanly vice is soil
A life refined by useful toil;
No dissipation leaves its sign,
No dark extreme to mar the line
Of noble virtues that proclaim
The record of an honored name.

Hail to our brother toiling still,
Life's blessed purpose to fulfill!
And ere my earnest rhyme is spent
In heartfelt wishes and intent,
From the sweet opening blossoms of spring
A modest garland would I bring,
And twine its blossoms with the lay
I sing upon his Natal Day!

E. A. P.

San Francisco, April 22, 1884.

Labor Items.

The Labor Bureau of statistics find difficulty in getting answers to the questions they send out. It seems that people do not care to disclose their operations.

Some 300 fishermen man the 1500 boats engaged in salmon fishing on the Columbia river.

At the Oakland nail works the green hands are still learning to do the work with the nail machines.

The harness makers and sash and blind makers complain of the competition of State Prison labor.

The season for building is just now commencing, and soon all our carpenters will have their hands full.

There is active inquiry for domestic labor. When the fruit and vegetable season opens, as it will shortly, there will be plenty of chances for our young people who are now idle.

A large proportion of the immigrants who arrive here are day laborers. Our local immigration association discourages this class, as there are so many here now and desires only to encourage those who wish to settle on the lands which may be cultivated.

The journeyman painters of this city have formed a benevolent organization for mutual protection and benefit, and also to co-operate with other labor organizations. Charles H. Ward was elected Chairman and J. M. Manning Secretary. After considerable discussion it was resolved that after the first Monday in May \$3.50 per day shall be the standard rate of painters' wages.

On Rock Drills.

(CONTINUED FROM PAGE 285.)

3,000 pounds per square inch. He has successfully overcome the difficulties at first encountered in the use of water under high pressure. The necessary machinery above ground is simpler and cheaper than any equally effective plant for compressed air, and consists only of a simple, quick-running pressure pump, run by a steam engine or by water-power, and of an accumulator. The useful effect of such a plant is not less than 71 per cent of the motive power employed, against 32 per cent in air compressors. In consequence of the high water-pressure the dimensions of the machinery become very small, the plant is cheap and the maintenance easy, compared with compressed air plants. [The cost of the plant at the Arlberg tunnel, where percussion drills were used on the east side and Brandt drills on the west side, amounted to \$161,494.49 at the east and to \$120,996.12 at the west end. These amounts include only the necessary machinery, but not the buildings, grading and water-power, furnish therefore a good base for a fair comparison. The difference in favor of the Brandt drill is \$40,503.37.] The loss of pressure through friction in the pipes is very small. All the disadvantages of the use of compressed air are avoided by the use of water under high pressure as motive power for rock drills and other underground machinery, and a number of direct advantages have been gained. In reference to ventilation, it has been shown above that even with compressed air a separate plant for ventilation is necessary. This is also the case with the hydraulic rotary rock drills, which, however, offer yet the advantage that water of high tension can be used to condense and absorb at once the fumes and smoke of the blast in such an effective manner that the face is accessible in a very few minutes after the charge has been fired. The fine spray of water creates a strong movement of the air. To use this most effective means of ventilation with any percussion drills worked by compressed air would require a separate plant. It has thus been shown that the transmission of power by water under high pressure and its application to rock drills and other underground machinery is not only practicable, but also superior to compressed air.

The rock drills of the present day can be divided into the following three groups: 1, percussion drills; 2, rotary drills with diamond bits; 3, rotary drills with steel bits.

Percussion Drills.

The percussion drill with the fore and backward motion works by the weight of the drill being thrown against the rock, exercising thereby such a pressure upon the same that its crushing strength is overcome and the rock is pulverized. The drill-bit is made to turn around its own axis, and an approximately round hole is made by frequent and quickly-repeated blows.

Diamond Drills.

The diamond drills rotate the bit rapidly and press with a low pressure against the rock. The drill hole is made only by the grinding and shaving action of the bit. The principle of this drill is based upon the greater hardness of the tool. The crushing strength of the rock does not play any part in the work of the diamond drills. They can never be used under high pressure, as the crushing strength of diamonds is small in comparison with that of other materials. These drills work better in homogeneous solid rock of uniform structure than in stratified rock of unequal hardness and consistency; they do not work at all in softer ground. This is the reason why the diamond drills occupy an isolated position among the rock drills. Their principle is different from that of any other drill, and permits their use only for deep hole drilling, and not for common tunnel and mining work. They cannot be considered rivals of the usual rock drills.

The rotary drills with steel bits—outside of the Brandt drill—are partly imitations of the diamond drills, and operate with spiral steel bits, which are rotated by some mechanical device, being simultaneously pressed against the rock, and producing the hole by combination of the shaving and pressing action of the boring tool. This kind of drills can be used only in soft material; in hard ground the pressure is not

sufficient, and the shaving motion wears off the steel points very rapidly.

The Brandt Drill.

The principle of the Brandt hydraulic rock drill is different from any of the percussion or rotary drills. Mr. Brandt uses in his drill a constant high hydraulic pressure, which presses the drill bit with such a force against the rock that the latter is crushed under all circumstances, as the crushing strength of hardened steel is greater than that of any known rock. [Hardest granite is crushed under a pressure of 19,662 pounds per square inch. The pressure upon one cutting edge of Brandt's drill is equal to 2,645 pounds, or to 56,384 pounds per square inch.] The points of the drill bit, provided the necessary pressure is applied, must also penetrate into the rock. In order that these points always exercise their pressure on fresh ground, they have to be rotated, by which rotation the rock is crushed and broken, but not pulverized and shaved. These two points: quiet high pressure on hardened steel, and slow rotary motion, to overcome the crushing strength of the rock, form the principles of the Brandt hydraulic rock drill. The pressure, being constant, and being exercised only in one direction, the mechanical labor required is less and the percentage of work accomplished is greater than in any percussion or rotary drill.

It has been proven that the actual useful effect is from three to four times greater in the Brandt drill than in a percussion drill. This makes it possible to use the Brandt drill where too little power is at disposal to employ percussion drills. The rod and bit of the Brandt drill is hollow, leaving a large core in the center.

BIRD'S-EYE VIEW OF JUDSON MANUFACTURING COMPANY'S WORKS.

In this way only the surface of a ring has to be worked upon. The core breaks during the drilling, according to the character of the rock, into longer or shorter cylindrical pieces. The core represents the amount of mechanical labor saved in drilling the hole. [For instance, take an annular drill-bit of 2½ inches outside diameter, and a hole 6 feet deep; then 155.28 cubic inches have to be worked down to make a hole of 427.68 cubic inches solidity, while with a percussion drill, starting in with a 2½-inch drill and finishing with a 1½-inch drill, 222.51 cubic inches have to be pulverized. This shows that a much larger result is obtained by the Brandt drill, with less labor, than in the percussion drill.]

Perfectly Straight and Cylindrical Drill Holes.

The holes made by the Brandt drill are perfectly straight and cylindrical, while those made by the percussion drills are conical and not always perfectly straight. The best form of hole to obtain the greatest effect of an explosive would be one which is wider at the bottom than at the mouth. [Alex. Von Humboldt already advocated the making of such holes.] Attempts have been made to make such holes, but they have not been successful. The perfectly cylindrical hole made by the Brandt drill is the nearest approach to it. This, in connection with the large diameter of the hole, explains the fact why only a small number of holes are necessary for the face of a heading.

Comparative Mechanical Power Required.

As a percussion drill necessarily uses a full drill-bit, and as the mechanical labor required rapidly increases with the diameter of the same, the largest hole which can economically be drilled by percussion drills is, at the mouth 2½ inches, and at the bottom from 1 inch to 1½ inches, the average diameter of the entire hole being 1½ inches. For instance:

A drill 3 in diameter made a hole 12 ft. deep in 72 min.
A drill 3 in diameter made a hole 18 ft. deep in 150 min.
A drill 1½ in diameter made a hole 12 ft. deep in 80 min.
A drill 1½ in diameter made a hole 15 ft. deep in 90 min.
A drill 1½ in diameter made a hole 18 ft. deep in 135 min.
A drill 1½ in diameter made a hole 12 ft. deep in 175 min.
A drill 1½ in diameter made a hole 15 ft. deep in 210 min.
A drill 1½ in diameter made a hole 18 ft. deep in 240 min.

Although these drillings were made by hand, they will serve to illustrate the increase of the mechanical labor required with the diameter of the hole.

The Effect of an Explosion.

It is therefore customary to drill a large number of holes of smaller diameter distributed all over the face. [At the Arlberg tunnel the average number of holes for one attack in the east heading (9 feet by 10 feet, percussion drills) was 32, with an aggregate length of 170 feet, while at the west side (Brandt drills) only 13 holes, with an aggregate length of 60 feet, were needed. The amount of power used was in either case nearly 70 pounds per one attack.]

The effect of an explosive increases rapidly with the area of the bottom of the hole. If P signifies the power, which tears the rock into fragments, p the initial tension of the explosive gas, and A the area of the bottom of the hole, then we have $P = pA$.

(CONTINUED NEXT WEEK.)

A Large Manufacturing Establishment.

We give on this page a little birds-eye sketch of the works of the Judson Manufacturing Company on the bay shore near Oakland, and adjacent to the overland track of the C. P. R. R. This company manages one of the largest, if not the largest, of our home manufacturing establishments. They employ regularly some 400 hands, and pay out from \$18,000 to \$20,000 a month for wages. We take especial pride in the Judson Company, because it is doing a grand work in demonstrating that California-made implements and hardware are

Debris Dams.

It will be remembered that Congress appropriated the sum of \$250,000, on the recommendation of Col. Geo. W. Mendell, of V. Corps of Engineers, U. S. A., for the improvement of the navigable rivers of California. The intention was to build a dam, or series of dams, to impound the tailings from hydraulic mines. The Secretary of War took the liberty of withdrawing this appropriation entirely, because he did not think it would do any good. This was a proceeding without precedent. The Chamber of Commerce of this city and the city of Sacramento now petition Congress to direct the expenditure of this appropriation as originally intended.

The matter came up in Congress this week. Budd made a long argument in favor of the appropriation to impound the debris as recommended by Col. Mendell. He dwelt at length upon the ruin likely to result to Sacramento from a freshet and described the deplorable condition of affairs, at present. In 1881, Col. Mendell recommended an expenditure of \$500,000 on the construction of wing dams and levees, but in his report this year he states that \$40,000 is all that he required to continue the operations of the snag boat. Budd criticised this change of base, and attributed it to a decision of the United States Circuit Court permanently enjoining hydraulic miners. But he thought that there was more necessity for the Government taking up the work now than before that decision. According to Col. Mendell's report there were 319,000,000 cubic yards of debris still lodged around the headwaters of the Sacramento and Feather rivers, and to wait until it was all washed into San Francisco Bay would cause a damage that could never be repaired.

Glasecock and Henley explained that at the time Col. Mendell had given up the idea of asking the United States to impound the debris, the State had passed a law to do the work itself, and it was thought the problem would be solved, but that legislation had been declared unconstitutional, and the matter was in its original position. If the river was to be saved, the Government must save it. Thomas of Illinois, a member of the committee, who said he owned a portion of a Yuba County hydraulic mine, and therefore spoke feelingly, gave his experience of a trip along the river some years ago. He endorsed Budd's description as accurate. In reply to questions by Willis, Budd stated that he would ask for the amount recommended by the engineers in 1881, which was \$500,000. Glasecock also spoke upon the condition of the Sacramento and Feather rivers, and described the gradual shoaling of Suisun Bay.

Industrial Notes.

Our woolen mills are not just now doing as favorably as they should. The business is somewhat depressed.

Red Bluff rejoices in an extensive sash-and-blind factory, where there are employed 70 to 125 mechanics, whose wages range from \$2.75 to \$4 a day.

The new steel works at Martinez are being pushed to completion. The erection of the main building is going ahead, and the boiler and engine-house are also well under way. The machinery has arrived, and the company has already some orders on its books.

The Arctic Oil Works, at the Potrero, are nearly completed. The buildings are up, the machinery is on the ground, and if all goes well operations will commence within a month or six weeks. The fleet of the company left port long ago to bring home, it is to be hoped, such a catch as will bring a material reward to the promoters of the enterprise.

Some Eastern capitalists are about to undertake the manufacture of alum from the waters of Alum Lake. The Walker Lake Bulletin says: The capital required will not be great, as the plant will consist principally of extensive evaporators. The water will be run on them as required, and, as wood is plentiful, the cost of crystallization will be but slight. Mr. Kimball has been appointed superintendent of the company, and will soon begin operations. Every day new uses are being found for the article, and, as it can readily be taken to market from Hawthorne, a profitable industry will doubtless soon be added to our other resources.

One of the largest flour mills in the country is in process of erection in this State, to meet the anticipated increased demand for California flour in Europe. We refer to the Starr mills, near Port Costa, on Carquinez straits, between San Pablo and Suisun bay. These new mills are of the most improved character and will have an immense capacity. Nearly two-thirds of all the flour shipped from here has gone to Great Britain and China. We send some also to Australia, the Pacific islands, Central America, Mexico, and some East. Our shipments by water in the last twenty years have aggregated 9,749,900 barrels. Hereafter, it is hoped, our flour exports will be larger and this branch of home industry will greatly increase its proportions. Just now, however, the flouring mill industry is depressed.

The Leaching Process.

(CONCLUDED FROM LAST WEEK.)

The Discussion.

Mr. C. A. Steefeldt of New York spoke concerning this paper as follows: The first thing we may note in this paper is that an ore was treated here containing 33.78 per cent of carbonate of lime. It has generally been assumed that silver ores, which contain such a large percentage of lime, could not be successfully chloridized, and especially not amalgamated, and also not successfully leached. I am inclined to believe that the analysis, as given here, does not represent the character of the ore which was treated on a large scale. The carbonate of lime in roasting is partly converted into sulphate of lime and partly into caustic lime, and caustic lime has a tendency to decompose chloride of silver and form metallic silver. Caustic lime, as well as other alkalis, has an injurious effect in leaching and in amalgamating.

I further remark that this analysis figures up exactly one hundred, and the silver is left out entirely. This is characteristic of Professor Price's analytical work (of which I had occasion frequently to see samples), that it always figures up exactly one hundred. And I suppose it is necessary in the West, because people would not be satisfied if the total per cent was not exactly one hundred.

In making a chlorination test of the samples, I see that Mr. Clemes uses a boiling concentrated solution of hyposulphite of soda. These chlorination tests are generally made with a cold solution, or at least with a moderately warm solution. It is also generally assumed that, in subjecting a sample of roasted ore to a chlorination test, only the chloride of silver is dissolved. This is not exactly true, especially if a warm solution of sodium hyposulphite is used, a great deal of silver is dissolved which is present in the metallic state. Mr. Russell, assayer at the Ontario mill for some time past, has investigated a great many chemical reactions of the leaching process, and has made especial experiments in regard to the solubility of different silver compounds in the hyposulphite solution. He finds that while a cold solution—say a solution at 15° Celsius—dissolves a comparatively small amount of metallic silver, a solution which is heated to 75° or 50° dissolves more than three times as much; so that, where we use a hot solution in the chlorination test, we not only get into solution the chloride of silver, but also metallic silver. And, furthermore, Mr. Russell found that also silver arsenate and antimonate are soluble in the hyposulphite solution, showing that really in all these tests it is not correct to speak of a chlorination test, but that it ought to be called a lixivation test. I have no doubt that, in roasting this ore, a great deal of metallic silver was really formed by the lime and went into solution in the leaching process. But, at the same time, I repeat that it seems to me doubtful that these results could have been obtained if the whole lot of ore treated contained over thirty-three per cent of carbonate of lime.

Dr. T. Eggleston, New York: I have read this paper with some interest, mostly because at present leaching appears to be the only

Process Applicable in the Case of Poor Ores.

Especially in those containing the base metals. So far as my own personal experience goes, these conditions are applicable to almost any low-grade ore, unless it contains a very large amount of lead, and so applicable to a large class of ores that cannot be treated in any other way.

I wish particularly to speak of the great tendency there is in the West to use too much salt. Too much salt, or more salt than is required, is a disadvantage. First, because its use increases the cost; and, secondly, it is a positive disadvantage in the lixivation. A very ingenious process has been invented by Mr. Hoffmann, of washing with hot water from the under side. By thus introducing the hot water from the bottom all the excess of salt is carried up, dissolving the silver as it goes. Then coming in contact with a great excess of water, the silver is precipitated on the top, and is left there as a crust, which contains almost all the silver which was dissolved.

I notice in this paper that the leaching was done from the top, and consequently all the extra salt went to dissolve out the silver, which must be precipitated from the leaching liquors. The bottom washing is a very ingenious contrivance to prevent this, to which special attention needs to be called. Where an excess of salt is used, and the leaching is not done from the bottom, and the washing water comes down through the ore, a considerable quantity of silver is found with the base metals precipitated. Where it is done from the bottom the silver is precipitated toward the top of the vat. A bullion which is comparatively pure is produced, as well as base metals from pure silver.

I would like to ask Mr. Steefeldt with regard to the results from his chloridizing furnaces. My own experience is with revolving furnaces that are eight feet long.

Mr. Steefeldt: The experiments which have been carried out lately by Mr. Russell

At the Ontario Mill

Give on an average from 93 to 94 per cent of the silver extracted by lixivation with Russell's solution, while the average by the ordinary

hyposulphite solution is only about 90 to 91 per cent. Some very curious experiments have been made in roasting Ontario ore in the Steefeldt furnace without any salt. The feeding of salt, which is crushed separately, was completely suspended, and the furnace was run for three hours without salt. After discharging the ore it was left for twelve hours on the cooling floor. About 89.7 per cent of the silver was lixivated from this ore by Russell's process, a part of which, namely, 17 per cent, was present as sulphate of silver, which would be extracted by water. Then about four or five per cent was present as native silver, and the rest as antimonate and arsenate of silver. From fahl-ore, which forms the principal silver-bearing mineral of the Ontario ore, and contains both antimony and arsenic, the last-named combination resulted. The way that this experiment on a large scale came to be made was this: I asked Mr. Russell to roast different ores in the muffle (oxidizing) and then try the effect of his new solution. About the composition of the latter I can say nothing here, because Mr. Russell's patents have not yet been granted. He took samples from the Ontario mine, from the Manhattan mines, from the Lexington mine, and from several others, and roasted about a pound of each in the muffle. The roasting was continued for half an hour, one hour, one hour and a half, two hours, two hours and a half, and three hours. A most remarkable fact was established in leaching these roasted samples, namely, the longer the roasting continued the less silver could be leached out. For instance, after half an hour he leached out thirty-one per cent, and after three hours he leached out only eight per cent. In another case, after half an hour he leached out sixty per cent, and after three hours only about five.

It appeared, from these tests, that the results were principally a function of time consumed in roasting. Hence the experiment on a large scale in the Steefeldt furnace was carried out.

Mr. Russell made this experiment in the Steefeldt furnace at a very high temperature, and I have advised him to repeat it at a moderate temperature. The muffle-experiments were also carried out in two ways, one series of experiments at a low red heat, and another at a cherry-red heat; and in every instance the high temperature had an injurious effect upon the extraction of the silver, and a low temperature had a beneficial effect. I have no doubt that, by roasting at a moderate temperature he will be able to extract 93 or 94 per cent of the silver.

Dr. Eggleston: There is another very curious thing about

Roasting With Salt.

In most ores the less salt that is used the better. There is a great gain in using a minimum amount of salt, and then leaving the material on the cooling-floor, as it has been found that chlorination continues in the heap long after it has left the furnace.

Mr. H. M. Howe, Boston: In oxidizing, as well as in chloridizing, roasting the decomposition of sulphurets goes on after they have been withdrawn from the furnace, and if they are heaped together, so as to keep hot, we find that after the lapse of a few hours the amount of undecomposed sulphurets has materially decreased. This is, no doubt, due to the reaction of sulphates, and even of oxides, present in the sulphur of the undecomposed sulphides yielding sulphurous acid and a low oxide of the metal; the sulphuric acid, and the previously formed oxides, which thus react on the sulphurets being reduced to a lower state of oxidation.

In some oxidizing roasts in an open reverberatory, on previously kiln-burnt Spanish pyrites, I found that the amount of copper existing as undecomposed sulphurets was diminished by 0.7 per cent while the ore was cooling in a heap outside of the furnace, the total copper contents being only about eight per cent. On this account it is very desirable to have pockets under or beside the furnace, where the ore can be kept hot for a long time after drawing.

Mr. Steefeldt: As far as the use of salt is concerned, that is exceedingly different with different classes of ores. I have succeeded in roasting ore with about two and a half per cent of salt, but with most ores such a low percentage is entirely insufficient. For instance, we have carried out a series of experiments at Ontario to determine the percentage of salt necessary. Five per cent of salt has no effect whatever. It is simply consumed without chloridizing the silver. Good chlorination only commences with ten per cent of salt, and chlorinations in the nineties cannot be obtained with less than sixteen per cent and more. Since at the Ontario mill salt costs only eight dollars per ton, one per cent of salt forms no item, and it has been found of advantage to use a surplus of salt.

Dr. Eggleston: I believe that in most cases, if the salt was reduced to 50 per cent, there would be a gain of 15 to 20 per cent in the chlorination.

Mr. Steefeldt: As far as the loss of silver is concerned in the leaching process, caused by the wash-water, that loss will vary according to the quantity of undecomposed salt in the ore, and whether hot or cold water is used. In Russell's experiments with Ontario ore, about three-fourths of one ounce of silver per ton of ore was lost in the wash-water. A large portion of this silver was regained by treating the first wash-water, containing also copper, with scrap-iron.

Cement-copper was precipitated with about 200 ounces of silver per ton.

Dr. Eggleston: Leaching from the bottom?
Mr. Steefeldt: From the top.

Production and Value of Nickel.

Price.

The price of metallic nickel in the market has been subject to considerable fluctuations, depending upon the variable demand and supply. The metal is to be viewed as a new material, a new gift to the industrial arts, with an unknown number of applications before it. The discovery of the cheap and effective methods of depositing nickel from solution by electricity, at once created a new outlet for a large quantity annually—a quantity which like the silver used in electro-plating is forever lost to the arts, not being capable of being economically regained, as is usually the case with alloys and objects made of solid metals. The demands for coinage also have not only been large, but have been sudden and transient, and have been the chief distributors of the average market price of the metal. The production of nickel has always been comparatively limited, in as much as the consumption has been uncertain and not firmly established by a long continued use of the metal in the arts.

Although the localities are numerous and wide-spread, the ores are not very rich and abundant, and it appears certain that the production of this metal will always require tedious, expensive processes, such as to make the item of labor an important one in the costs of production. This will always give the metal a high value, as compared with iron or copper, and makes it on this account, as on others, well adapted to use as money, it being so largely a representative of labor performed.

According to Wharton, the extremes in the price of nickel in England, since the metal attained commercial importance up to about the year 1877, were from 4s. to 16s. per pound—say \$1 to \$4 per pound. The former rarely touched, and the latter but once for a short time in 1873. In the year 1861 nickel was quoted at from \$1 15 to \$1 20 per pound. In 1864 it was quoted at 8s. in England, and in 1867 in France at 1,500 to 1,700 francs per 100 kilogrammes, or 7½ to 8½ francs per pound. The price in England, in 1883, was quoted in a memorial to Congress at the equivalent of 70 cents per pound.

Mr. J. M. Merrick, in his excellent article upon nickel in Johnston's Cyclopaedia, gives a tabular statement showing the range of price of nickel per pound in large lots for a series of years from 1870 to 1876, as follows:

Price of Nickel from 1870 to 1876.

Years.	Prices.
1870.....	2 00 to \$1 20 currency.
1871.....	1 50 to 1 00 currency.
1872.....	2 25 to 1 20 to 1 00 currency.
1873.....	3 25 to 1 10 currency.
1874.....	2 80 to 1 10 currency.
1875.....	3 00 to 1 10 currency.

The following figures give, in continuation of the preceding, the average market price of nickel in the United States from 1875 to January 1, 1883, a period of seven years:

Price of Nickel from 1876 to 1883.

Years.	Prices.
1876.....	\$2 00 gold.
1877.....	2 00 to \$1 20 currency.
1878.....	1 20 to 1 00 currency.
1879.....	1 15 to 1 10 currency.
1880.....	1 10 currency.
1881.....	1 10 currency.
1882.....	1 10 currency.
1883.....	1 10 currency.

The market price at the end of the year 1882 was \$1 10 per pound, and in May, 1883, about \$1 per pound, wholesale. Reductions or discounts are made by foreign makers to their large customers in the United States, the amount of which in each case is not known.

The extreme prices in the United States for ten years prior to 1877 were, according to Mr. Wharton, about \$1 40 and \$2 80 gold for large contracts. The nickel then made contained about five per cent more impurities than the best since made, which contains 98 per cent or over of pure nickel.

In the years 1874, 1875 and 1876 the German government paid an average price of about 10s. 6d.—say \$2 62 gold per pound for the nickel in the planchets for coining. The extraordinary demand for the metal from this source carried the price for a time abnormally high, to \$3 50 per pound. During that period the German government consumed in coinage over 800,000 pounds of nickel (380,748 kilogrammes up to January 6, 1877, not including waste), purchased as planchets ready for stamping. The relative value of nickel and silver, taking 54d. per ounce for standard silver, or 58½d. for fine, and 5s. per pound for nickel, is as 1 to 14.18.

Production in the United States.

Before the year 1864 the whole amount of pure nickel made in the United States was not over 100,000 pounds avoirdupois. Since then, to May, 1867, the Camden works turned out 105,000 pounds, and they were at that time producing at the rate of 105,000 annually.

The total production of nickel from the Gap mine to the end of the year 1882 is estimated at 4,000,000 pounds. It is not now being worked, having been shut down since January, 1883, and there is now, therefore, no production to record for the first portion of the year 1883.

The total production of nickel from the Gap mine to the end of the year 1882 is estimated at about 4,000,000 pounds. It is not now being

worked, having been shut down since January, 1883, and there is now, therefore, no production to record to the first portion of the year 1883.

The production of pure grain metallic nickel in the United States for seven years past, from 1876 to 1882 inclusive, aggregates 1,466,765 pounds, an annual average of 209,538 pounds, as shown in the following table:

Annual Production of Nickel in the United States since 1876 (pure grain nickel.)

Years.	Pounds.
1876.....	201,367
1877.....	188,211
1878.....	150,590
1879.....	145,120
1880.....	233,893
1881.....	265,068
1882, nickel.....	277,034
50 per cent. alloy, nickel therein.....	4,682

Total for seven years.....1,466,765

The consumption of nickel in this country for the first six months of 1883 is hard to give with accuracy, but it may be estimated at not less than 150,000 pounds.

Production in Europe.

The annual production of nickel in Europe in 1873 was estimated by Messrs. Maw and Dredge, the reporters on the metallurgical exhibits at the Vienna Exhibition, to be but about 500,000 pounds, and in America 200,000 pounds. The greatest producers of nickel in Germany at that time were the Saxony Cobalt Company, at Oberschlema and Pfannenstiel, near Schneeberg, in the Saxon Erzgebirge, which turned out over 10,000 pounds of pure metal.

The production of nickel ores and spies in the principal countries at the time of the International Exhibition in Paris, 1867, was, as nearly as could be ascertained from the official reports, as follows:

England (ores).....	Tons.
Austria (ores).....	1,745
Prussia (ores).....	600
Nassau (spies).....	250
Saxony (spies).....	52
Italy (spies).....	15
United States (ores).....	7
Sweden and Norway (spies).....	2,350
	150

The total annual product of metallic nickel in all countries was estimated in 1877 to be about 1,200,000 pounds or 550,000 kilos. Mr. Wharton's establishment at Canby then supplied about 260,000 pounds, or one-sixth of the entire product.

Recent Contributions to the California State Mining Bureau.

(Furnished for publication in the MINING AND SCIENTIFIC PRESS BY HENRY G. HANKS, State Mineralogist.)

[CATALOGUE.]

- 5276. Encino (Live Oak)—Honduras wood. M. A. Soto.
- 5277. Nance—Honduras wood. M. A. Soto.
- 5278. Tegajale—Honduras wood. M. A. Soto.
- 5279. Roble Blanco (White Oak)—Honduras wood. M. A. Soto.
- 5280. Gualabillo—Honduras wood. M. A. Soto.
- 5281. Alazan—Honduras wood. M. A. Soto.
- 5282. Cacha de Concepcion—Honduras wood. M. A. Soto.
- 5283. Refined Borax—Refined by the Harmony Borax Company, in Alameda Co., Cal. Presented by the company.
- 5284. Kaolin—Sections 4 and 5, township 16 north, range 8 east, Nevada Co., Cal. Millen Ford.
- 5285. Kaolin—Baked in potter's oven, by Gladding & McBean, and pronounced by them to be a good white burning clay, or kaolin. From the deposit No. 5284, Nevada Co., Cal.
- 5286. Refined Borax—Manufactured by the San Bernardino Borax Mining Co. (See No. 5379).
- 5287. Rock Specimen—Hanging wall, Nevada City mine, 600-foot level. (See No. 4853). The mine is situated one mile and a half from Nevada City, Nevada Co., Cal. E. P. Heald.
- 5288. Rock Specimen—Foot wall of the Nevada City mine, one and a half miles from Nevada City, Nevada Co., Cal. (See No. 5287). E. P. Heald.
- 5289. Sulphurets Ore, with visible free gold—Nevada City mine, one and a half miles from Nevada City, Nevada Co., Cal. (See No. 4853). E. P. Heald.
- 5290. Refined Borax, from Peck's Marsh, Esmeralda Co., Nev. Smith Brothers.
- 5291. Borate of Lime (Ulexite)—Desert Springs Lake, Kern Co., Cal. Boracic Acid Manufacturing Co., J. B. Hobson, Superintendent.
- 5292. Borate of Lime (Sheet Cotton)—Desert Springs Lake, Kern Co., Cal. J. B. Hobson.
- 5293. Boracic Acid (98.8 per cent)—Boracic Acid Manufacturing Co., J. B. Hobson, Superintendent. (See No. 5291).
- 5294. Iron Ore—Found in large quantities at Tepache, 10 miles from Culiacan, Sinaloa, Mexico, with an abundance of water and water. James D. Schuyler.
- 5295. Tooth of a Horse—Found on a creek that empties into the river, Humboldt Co., Cal., in a soft stone which seems to be siliceous. It is probably fossil. The remains of fossil horses have been found in abundance in Oregon. R. E. Herick.
- 5296. Limonite Crystals, after Pyrite (containing gold)—Butte Co., Cal. Mrs. Charles Slocum.
- 5297. Borate of Lime (Sheet Cotton)—From which boracic acid is made. (See No. 5291). From Desert Springs Lake, Kern Co., Cal. (Described folios 29 and 81, Part II, Third Annual Report of the State Mineralogist. Presented by the Boracic Acid Manufacturing Company, J. B. Hobson, Superintendent.
- 5298. Crude Borate of Lime—Variety known as Sheet Cotton (described folio 83, Part II, Third Annual Report of the State Mineralogist). From Desert Springs, Kern Co., Cal., and presented by Boracic Acid Manufacturing Co., J. B. Hobson, Superintendent.
- 5299. Ammonite—Found in the mountains, Placer Co., Cal. John Hensley. (See letter on file.)
- 5300. Agalutinites (?)—Some what resembling the Chinese Figure Stone, and similar to a rock from San Luis Obispo. (No. 4994). This beautiful ornamental stone is found two miles west of Greenwood, Eldorado Co., Cal., in a vein from six inches to a foot in thickness. Alex. Keller.
- 5301. Yellow Ochre, of good color and quality—Found in large quantity on section 32, township 12 north, and range 11 east, four miles east of Georgetown, El Dorado Co., Cal. E. H. Watson.
- 5302. Silver-Gold Ore—340-foot level, Oro mine, Bodie, Mono Co., Cal. T. Steel.
- 5303. Silver-Gold Ore—440-foot level, Oro mine, Bodie, Mono Co., Cal. T. Steel.
- 5304. Silver-Gold Ore—520-foot level, Oro mine, Bodie, Mono Co., Cal. T. Steel.
- 5305. Silver-Gold Ore—750-foot level, Oro mine, Bodie, Mono Co., Cal. T. Steel.
- 5306. Horns of the Mountain Sheep—Ovis Montana (Cuv.) called, also, Big Horn—Wild Rose District, Telescope Range, Inyo Co., Cal. Capt. J. M. Keeler.
- 5307. Models of Mining Tools—Made and presented by F. O. Shuter.
- 5308. Models of Mining Tools—Presented by Isaac Blum, one, Jr.

PHILADELPHIA MANUFACTURING INDUSTRIES: There were built in Philadelphia in 1883, no less than eighty-three factory buildings and eighty foundries and machine shops, and this notwithstanding the general depression of manufacturing industries throughout the country.

Prospective Boom.

The *Cœur d'Alene* are not destined to monopolize the mining excitement this year, if whispered rumors are to be credited. The air is filled with mysterious suggestions of other fields which are plethoric with gold. Whether these rumors will culminate in anything tangible is far more uncertain than the prospects in our hill diggings or the chances for mammoth quartz mills at a dozen points on Pritchard and Eagle. But it is well to be posted regarding rumors, and we give them as they come, leaving our readers to draw their own conclusions. The first and best authenticated story is that rich gold-bearing placer and quartz ledges have been discovered about fifty miles to the south-east, on the St. Joseph river. This rumor bears the stamp of truth, as the formation is similar to that of the *Cœur d'Alene* region, and there seems no good reason to doubt the existence of valuable mines in that section as well as this. Should developments justify, the rush will doubtless extend to the St. Joseph country.

Rumor number two is located far to the northward, in the Kootenai country, between the Northern Pacific and the British possessions, and extending across the line. This country is known to be in the mineral belt, and may prove rich in precious metals. It is possible the Northern Pacific may wish to extend a branch in this direction, and that may have something to do with the whispers that are being circulated.

Number three is in the direction of the Flat-head reservation, eastward from here, and farther away. This is perhaps the vaguest of the rumors, but may not be entitled to the least credence.

The fourth comes from Snake river, and has as yet assumed no tangible form. Certain it is that the coming summer will witness a thorough prospecting of northern Idaho and Montana. Eagle will be the radiating point, and, so far as heard from, will form the center and nucleus of the new discoveries. All is for us that is not against us, and we shall be glad to learn that rich fields exist in every direction. Every gulch and hillside, every flat and mountain, will be searched over and over before the year closes, and it will be strange indeed if much pay dirt and many a good ledge is not brought to light. It has for years been an open secret that good prospects could be found throughout a vast track of country of which the *Cœur d'Alene* forms a part. There is ample room for prospectors, and many a grub stake will be furnished to those who are willing to endure the hardships and explore the mountains. "Unprospected" could be printed on the greater portion of the map of this entire country. Prospectors are too eager to wait for the snow to go off, and even now are scattered far and wide through the hills. As soon as the snow disappears the search will be general and very thorough. It took nerve and perseverance for Pritchard and Gilatt to make their discoveries, but now that the glitter of gold has caught the prospector's eye, nothing can prevent every nook and corner of all this vast country from being carefully worked.—*Cœur d'Alene Nugget*.

Mill City Reduction Works.

One of the Best Quartz Mills in the State.

R. L. Fulton took a look at the new reduction works at Mill City and gives the result of his observation in the *Gazette*. He says: Humboldt county has not had as good a prospect for years as it has to-day. There are many mines that look well, and the facilities for working them are increasing all the time. The Mill City Reduction Works will be completed in a few days, and by May 1st will be working ores. Any kind of rock can be handled as they have stamps and furnaces both. The ore first strikes a Blake improved crusher, that can handle $4\frac{1}{2}$ tons an hour. A belt and bucket elevator carries the ore to a bin high enough to be led through pipes, either to the dry kiln or the battery. The latter crushes it coarsely, but fast. It has five stamps and very coarse screens. From it the ore goes to a set of Krom rolls, that make 100 revolutions a minute and crush 25 to 30 tons a day, so that it goes through a 40-mesh screen. The rolls are of 16-inch face, 26 inches in diameter, and, with the frame, weigh seven tons. Mr. O'Donnell has introduced an improvement in them that adds to their power. They are new to this section, only being used at Mt. Cory and a mill near Eureka. There are four pans and two settlers below the rolls. If the ore is roasted it goes from the rolls through another elevator to a belt and screen, which throws it into the O'Hara furnace, where 30 tons a day can be handled. It is 50 feet long, and has two plows to turn the ore on the bed. Each plow moves it forward three-fourths of an inch. These plows can be regulated so that the ore can lie in the furnace any time from six to 22 hours. The ore falls into pits and is pulled out into the cooling floor. The power is supplied by a fine steam engine. The boiler will burn sagebrush and the furnace cedar and pine. The iron foundry is to be moved to the east side of the mill, and far enough away to be out of danger of firing the mill. The works are owned by James Gould and James O'Donnell, who are doing most of their work themselves. They can work ore very cheap, and anything that has \$30 in it can be made to pay. They will work ore in 1,000-ton lots for \$15 a ton.

USEFUL INFORMATION.

Uneven Shrinking.

Much loss is occasioned in the foundry by uneven shrinking of castings, causing distortions and fractures. Some of these may be avoided by previous preparation in the construction of the patterns. Rimmed wheels with arms, like pulleys and gears, are particularly liable to these shrinkage losses. This is because the continuous rim and the solid hub retain their heat longer than the separated and comparatively light arms. The remedy that suggests itself is to make these arms longer, so as to allow them more shrinkage. Obviously the only way to lengthen the arms is to make them dishing, instead of having them run on a straight line from rim, through the hub, to rim, deflect them out of a right line, having the result of making a dished wheel, the hub being out of line with the edges of the rim, and the arms on a corresponding slant. The amount of this "dish" or drop of the hub should be about that of the estimated shrinkage of cast iron—one-eighth of an inch to the foot. Thus, a pulley of twelve inches diameter and six inches face should be dishd by the pattern-maker so that the hub drops about one-eighth of an inch below the level of the pulley rim edge.

Pulleys and gears cast with these dished arms come straight on cooling, and they do not require to be uncovered, or partially uncovered, in the mould to facilitate even shrinkage. Every machinist knows what annoyance he has suffered from the chilling of cored hub holes and of the rims of pulleys, the core hole in the hub being sometimes swabbed while red hot, and the sand from the rim dug away, making much trouble in boring, and necessitating the grinding of a pulley face instead of turning it.—*Scientific American*.

SOFTENING WATER.—An account is given in the *Engineer* of a method of softening water followed in some industrial establishments in Germany. The principle of the process is based upon the fact that heated and hydrated oxide of magnesia readily absorbs the free carbonic acid of natural water; and by thus depriving the water of its dissolved gas, precipitates the carbonate of lime previously held in solution. The magnesia then dissolves, and unites with the bicarbonate of magnesia in the water. At first, water thus softened was suspected of attacking old boilers fed with it, and filling them with mud. It was afterwards found, however, that it was the old hard scale that had been dissolved into mud; thus exposing any weak places and leaks that might have been corroded over before the purified water was introduced. The water thus treated has an alkaline reaction, and counteracts any possible acid corrosion. At first, stirring was considered an indispensable part of the process; but, eventually, it was found that straining the water, through an excess of the hydrated oxide of magnesia spread on a filtering medium, would produce the desired effect without further trouble. By mixing proportionate quantities of finely powdered oxide of magnesia and saw-dust with water, and subsequent heating, hydrated oxide of magnesia will be formed throughout the whole mass. This preparation forms a most valuable filtering material. Metal cylinders are tightly filled with the mixture and used as filters; and they are efficient, not only in cleaning dirty water, but also in softening it, for the carbonate of lime crystallizes directly upon the sawdust.

PREPARING NUTS FOR THE TABLE.—A correspondent of the *Herald of Health* writes that journal as follows: I have just discovered that soaking the smaller kinds in fresh water for three or more days, as required, gives them a freshness otherwise unattainable. There is a nut rather plentiful at the present time, at various fruiterers, called by several names, such as "Turkish filberts," etc. It is a long nut and filbert-shaped, in color of shell resembling Spanish or Barcelona nuts. I bought some already soaked, which were the nearest approach to fresh filberts I have tasted. My fruiterer tells me that old Brazils, if good, may be treated the same (but need longer soaking). I am experimenting. Nuts must be well masticated, or will prove indigestible.

GEMS FROM BLAST FURNACES.—Gems from refined blast furnace slag are on exhibition in a Wall street jewelry store in New York. These cut and set stones have the hardness of natural silicates and the brilliancy of the much softer lead-glass, or "strass," of which the so-called "Parisian Diamonds" are made. What their value as artificial gems may be is of less importance than the fact that they are made of American blast furnace slag, the raw material being the usual cinder of foundry and Bessemer pig iron from anthracite furnaces in New York and New Jersey.

THE NEW GLASS invented in Vienna seems to have proved a success in the qualities claimed for it—that is, it is transparent and more brilliant than common crystal, can be cut and polished, and when fused, adheres to iron, bronze and zinc. Singularly enough, the glass differs from all others, new or old, in that its composition includes none of the usual ingredients—silica, potash, soda, lime or borax.

A **USEFUL INSTRUMENT**, which will doubtless become a necessity in certain lines of manufac-

turing, is being introduced in England. An electric system is established throughout a factory, which, through the agency of an indicator placed in the office, shows at a glance whether the different looms or machines in the building are in operation.

TO MEND RUBBER CLOTH. Any one who has had the misfortune to injure the coating of a rubber umbrella will be glad to know that it is not without remedy. A preparation of damar varnish and asphaltum in about equal quantities, with a little turpentine, will make an easily applied coating, which makes the umbrella about as good as new again. Spots on gossamer coats and cloaks can be covered with this also.

THE "SETTING OF GYPSUM" is the result of two distinct phenomena. On the one hand, portions of anhydrous calcium sulphate, when moistened with water, dissolve as they are hydrated, forming a supersaturated solution. Again, this same solution deposits crystals of the hydrated sulphate, gradually augmented in bulk, and unite together.

BUMPING CARS.—When riding in a railway car that bumps along like a country wagon over a corduroy road, you may infer that the wheels are not as round as they ought to be. Putting the wheels of a hard-riding car in a wheel-grinding lathe and truing them, will be found a very effective method of giving passengers a smooth, pleasant ride.

LUBRICANT FOR HEAVY BEARINGS.—The following is said to be a good lubricant for heavy bearings: Dissolve the best of white lead in good machine oil, make it pretty thick, take all the hard and clotty substance away, then add the remainder, and you will find a good lubricant.

WATER-PROOF VARNISH FOR IRON.—A varnish compound of 120 parts of mercury, ten parts tin, twenty parts green vitriol, 120 parts water and 15 parts hydrochloric acid of 1.2 specific gravity, furnishes a good coating for iron exposed to the wet.

CHEAP FIRE-PROOF ROOF.—A German paper says that a roof can be made fire-proof by covering it with a mixture of lime, salt and wood ashes, adding a little lamp black to give a dark color. This not only guards against fire, it is claimed, but also in a measure prevents decay.

THE substitution of hemp rope for pelting is becoming common in England. Large grooved pulleys and rope two to two and a quarter inches in diameter are used. There is said to be a vast difference in cost in favor of rope.

THE FIRST CARTRIDGES were made in China fifteen hundred years before the dawn of the Christian era. They were used at great festivals simply in pyrotechnic displays, and of course were all "blanks."

GOOD HEALTH.

Exercise as a Remedy for the Nervous.

Dr. Oswald writes in *Popular Science Monthly*: "When I reflect on the immunity of hard-working people from the effects of wrong and over-feeding," says Dr. Boerhaave, "I cannot help thinking that most of our fashionable diseases might be cured mechanically instead of chemically, by climbing a bitter wood tree, or chopping it down, if you like, rather than swallowing a decoction of its disgusting leaves." For male patients, gardening, in all its branches, is about as fashionable as the said diseases, and no liberal man would shrink from the expense of a hoard fence, if it would induce his drug-poisoned wife to try her hand at turf-spading, or at hoeing, or even a bit of wheelbarrow work. Lawn tennis will not answer the occasion. There is no need of going to extremes and exhausting the little remaining strength of the patient, but without a certain amount of fatigue the specific fails to operate, and experience will show that labor with a practical purpose—gardening, boat-rowing, or amateur carpentering—enables people to beguile themselves into a far greater amount of hard work than the drill-master of a gymnasium could get them to undergo. Beside the potential energy that turns hardships into play-work, athletics have the further advantage of a greater disease-resisting capacity. Their constitution does not yield to every trifling accident; their nerves can stand the wear and tear of ordinary excitements; a little change in the weather does not disturb their sleep; they can digest more than other people. Any kind of exercise that tends to strengthen—not a special set of muscles, but the system in general—has a proportionate influence on the general vigor of the nervous organism, and thereby on its pathological power of resistance.

For nervous children my first prescription would be—the open woods and a merry playmate; for the chlorotic affections of their elder comrades—some diverting, but without fatiguing, form of manual labor. In the minds of too many parents there is a vague notion that rough work brutalizes the character. The truth is, that it regulates its defects; it calms the temper, it affords an outlet to things that would otherwise vent themselves in fretfulness and ugly passions. More school teachers know that city children are most fidgety, more irritable and mischievous than their village comrades; and the most placid females of the genus homo are

found among the well fed but hard-working housewives of German Pennsylvania.

AN AID TO CURING ALCOHOLISM.—A contemporary writes: We believe the best authorities are generally skeptical as to there being any sure cure for confirmed habits of inebriety unless the effort in that direction be aided by a strong exercise of the will of the unfortunate subject of the bad habit. There are, however, many remedies recommended as aids in diverting or in a minor degree satisfying the appetite for strong liquors, which are undoubtedly of great advantage in some cases, and one of these is thus recommended by a self-styled "rescued man": "I was one of those unfortunates given to strong drink. When I left it off I felt a horrid want of something I must have or go distracted. I could neither eat, work, nor sleep. Explaining my affliction to a man of much education and experience, he advised me to make a decoction of ground quassia, a half ounce steeped in a pint of vinegar, and to put about a small teaspoonful of it in a little water, and to drink it down every time the liquor thirst came on me violent. I found it satisfied the cravings, and it sufficed a feeling of stimulus and strength. I continued this cure, and persevered till the thirst was conquered. For two years I have not tasted liquor, and I have no desire for it. Lately, to try my strength, I have handled and smelted whisky, but I have no temptation to take it. I give this for the consideration of the unfortunate, several of whom I know have recovered by means which I no longer require."

A BLIND MAN ON THE CARE OF THE BLIND. At a recent entertainment given in London to 200 blind persons, Postmaster-General Fawcett, who is himself totally blind, remarked: "Within the last few years I believe there has been remarkable improvement in the methods adopted in many of the institutions for educating the blind. To take one example—and others might be selected—I believe that of the pupils who leave the Normal College for the Blind at Norwood, about 80 per cent maintain themselves in after life. With regard to those who become blind when they are adults, very different considerations apply. I believe it is found that the fingers very soon lose that marvelous dexterity of touch which many of the young blind possess, and that, consequently, the adult blind cannot be trained in the same manner. With regard to those who become blind in after life, the one thing which, above all others I wish to enforce, is, do not take them away from the joys and pleasures of home life, do not keep them within the walls of institutions, do not congregate them together, but let them live, as far as possible, with those who can see."

COOLNESS AND FEAR IN WOMEN.—A writer describes in one of our daily papers a scene at a hotel in Saratoga during a fire, with the coolness and self-possession of some of the women, and the fright of others. He made some inquiries as to the character and training of both classes, and found that those who were self-possessed were the business women and those who had received physical culture, while the frightened ones were the daughters of wealth, luxury and idleness. It is certain, however, that not all the daughters of wealth are timid, nor all those who work brave. It is partly a matter of education and training and partly a matter of birth and inheritance. Such hasty conclusions from hurried observations would not count for much in a careful study of such a question.

CONTAGIOUS BALDNESS.—A German physician contends that premature baldness is usually a result of contagion. He claims that the hair is destroyed by a fungus which is communicated from one head to another by means of combs and hair-brushes. The remedy recommended is washing the scalp daily with tar soap, afterward bathing it with warm water for some time, and then drying the hair and applying a weak solution of carbolic acid. A one or two per cent solution is of sufficient strength. The wash should be continued six or eight weeks, and is said to be successfully employed when the hair first begins to fall out.

ALCOHOL AND DIGESTION.—We see many preparations of which the chief virtue is supposed to be that they contain *all* the digestive principles. These can be active only so far as they contain pepsin, and have no advantage over the simple drug. It has also been shown that certain substances combined with pepsin in solution render it inert. Alcohol is one, and even in moderation diminishes its action, while, in any quantity, the activity of pepsin is totally prevented. This is a point often lost sight of, and serves as a hint concerning the use of liquors at meals, by dyspeptics.—*Med. Rep.*

HALF THE SEX INVALIDS.—Our dainty notions have made women such a hot-house plant, that one-half the sex are invalids. The mothers of the next generation are invalids. Better that our women, like the German and Italian girls, should labor on the highway, and share in the toil of harvest, than pine and sicken in the indoor and sedentary routine to which our superstition condemns them. But I leave this sad topic for other hands.—*Wendell Phillips*.

IVY POISONING.—In cases of poisoning with poison-ivy, paint the affected parts as soon as possible with a mixture of quick-lime and water. The mixture should stand half an hour after the lime and water are put together.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

DOWNS.—Amador Ledger, April 19: Prospecting is the work in hand at the mine near Volcano. The ore-body in the upper level of a paying quality has been pretty well exhausted, and it is now necessary to prospect at greater depth. Confidence is felt, however, that the researches will be crowned with further important developments.

MISCELLANEOUS.—The weekly cleanup at the St. Julian mill last Sunday was satisfactory, although not so productive as previous runs. The big tunnel at Middle Bar was partially flooded last week by a break in the ditch, causing the water to pour down a small gulch and over the mouth of the tunnel. The workmen inside were apprised of the mishap by the water backing up and covering the floor of the tunnel to a considerable distance. The building in which the air compressor and blacksmith shop are located was made the repository of a lot of debris, but no serious harm was done, and the works were soon placed in running order again. A water blast has been placed in the tunnel to drive the smoke from the head. This is merely a temporary expedient until a first class blower arrives. The head of the tunnel is in hard granite, distance nearly 800 ft from the mouth.

El Dorado.

PROSPECTING.—Placer Herald, April 16: A. H. Dake, who is an old resident of Auburn and an experienced miner, has been employed by a rich and influential company to prospect the country in the neighborhood of Greenwood, El Dorado county. He has returned to Auburn after an absence of one month. During his absence he has passed over a great tract of country in the vicinity of Greenwood, and has ascertained, as far as could be done in so short a time with limited facilities, the mineral condition of the country, and has satisfied himself that the mineral wealth of that district is very abundant, and if the company he represents meets with the necessary encouragement, they will immediately take such measures as are necessary to fully develop the mineral resources of that portion of the State. Like all other mining localities, there are a number of individuals who own claims that are entirely undeveloped, and want to sell them at exorbitant prices, which, if persisted in, will prevent the company Mr. Dake represents from opening up the mineral resources of that district, which, he is satisfied, would make Greenwood a very lively mining camp and add greatly to the prosperity of the town.

SLATE MOUNTAIN.—Cor. Mountain Democrat, April 11: All our people are manifesting an interest in the famous Slate Mountain mine. This mine is under the superintendency of D. Monchton, and having been thoroughly tested, promises to be a "bonanza" in earnest. They have expended much capital in grading a road and erecting a bridge over Rock creek. They intend, within forty days, to have a mill erected.

Modoc.

ORE.—Cor. Adin Argus, April 12: A vein of good paying ore is reported to have been struck in the "Gopher." This claim lies in the flat south of the Hill, and formerly belonged to Stearns & Driskell. Frisby Hoes has about 300 tons of ore on his dump. It is not of as high a grade as that formerly worked from the mine. He is now, however, working at a greater depth and extracting a better quality of ore. Mr. Hoes expects to have his new mill ready to run by the 15th prox. The Lewis & Harbert, Juniper and Golden Eagle are working with about the same degree of success as when last reported. The Blue Bell Co. have good pay in sight.

Mono.

TRAMWAY.—Homer Mining Index, April 19: Both of the Bodie papers give currency to a report that a tramway is to be built from the same point near the old toll house on the Lake Canyon road to the May Lundy mill, to facilitate the transportation of ore. With the additional five stamps that are to be put into the mill at once, the extension of the lower tunnel of the May Lundy into Lucky Morton ground, and the starting of additional stopes therefrom, and the opening of the Lake View—all of which projects enter into the calculation for the coming summer's work—such a structure as the proposed tramway would become a necessity, besides greatly reducing the time and cost of transportation. It is stated on the best of authority that the Gorilla Mill and Mining Company has already purchased (or had made to order) in San Francisco a new mill, and that it will be shipped here just as soon as the roads become passable. The mine is being put in order for vigorous operations, and as the legal obstacles to obtaining a patent are rapidly vanishing, the company now seems to be on the high road to prosperity. The new mill is to be put up at the foot of the tramway, so that the ore can be run right from the mine to the batteries by car.

Nevada.

QUARTZ MINING ON THE RIDGE.—Nevada Transcript, April 14: W. L. Thurston came down from the San Juan ridge Saturday to get supplies. He says that prospecting for quartz is being actively pursued in the vicinity of Cherokee. The claim of Thurston Bros. is looking well. They are down 40 ft on the ledge—the deepest quartz mining ever done in that locality. The ledge is 16 inches thick, and there is a good-sized crushing on the dump. The Cannon-ball quartz mill being erected by Thurston Bros. will be ready to start by Thursday. It has a capacity of six tons in 24 hours, and is to be run by water power. At Badger hill, Brophy, Lang & Co. have a two-foot ledge that shows well in free gold. They have fifteen tons of ore out, and will crush it as soon as the Cannon-ball mill is ready. There are four or five more companies prospecting within a radius of four miles of Cherokee. Most of them are taking out quartz which they propose to have crushed at the same mill.

CHAMPION MINE.—The twenty-four tons of rock crushed at the Merrifield mill for the Champion Co. yielded \$25 per ton. Considering the large ledge there is no reason why the Champion should

not soon rank as one of the solid mines of this district.

Plumas.

CLEAN-UP.—Plumas National, April 16: Mr. W. Holmes cleaned up a few days ago, and for ten days' work showed eight and one-half ounces of nice dust. To-day he showed us \$8 worth for half a day's work. He says the bedrock in his claim is "lousy" with it.

San Bernardino.

PROVIDENCE MINE.—Calico Print, April 19: During the past month two new strikes have been made in the Bonanza King, showing large bodies of rich ore. The output from the mine is regular as clock-work, and the company's mill is running with a steadiness that nothing but able superintendency would guarantee. The Bonanza King Co. have been happy in the selection of their officers here in charge. Mr. E. Huhin, the Supt. of the mill, has shown himself to be the metallurgist of the coast. Mr. Callaghan, who has had charge of the mines for the past few months, shows much capacity. The selection of the working force indicate a poor showing for the saloon keepers. Mr. Morris S. Bates, as Secretary and Treasurer of the company, has, by his gentlemanly, courteous manner, won the good will of all those that come in contact with him. R. P. Kerr's big prospect, north of the Bonanza King about half a mile, is running through a large body of a high grade ore, from a shaft down about 40 ft. He has drifted east and northeast about 27 ft showing a continuous body of ore. He has a small force of men taking out for shipment which would have been shipped ere this but for one thousand storms here. The assays made are said to run up in the hundreds. The Kohinoor Co., which lies in between the Bonanza King and R. P. Kerr's mine, has a shaft down about 57 ft, having run through a vein of fine ore which dipped to the east. The company has not yet crosscut for the ledge. The owners of the Belle McGilroy mine continue to take out good paying ore, and are prospecting their mine thoroughly. The mine has a large quantity of ore on their dumps, with a large amount in, and bids fair to be another Bonanza King. Several other locations are looking very fine for the amount of work done. The Mozart, Lucknow and Mineral Point, and further south the Belle McGilroy and the Treasury and Morning Star lies in between the Bonanza King and the Belle McGilroy. There has an impression got abroad—no doubt spread by parties who are desirous of getting hold of some properties—that the water in camp is owned by the Bonanza King Co. Such is not the case; there are quantities of water for milling purposes. Messrs. J. B. Cook and Thompson have a large supply of water, and only had to sink about 25 ft. Dwyre and Gorman are the owners of a large spring of water running down the canon half a mile, and Mr. S. A. Barrett and others have water in the same neighborhood which is all close to the mines. The weather here has been unusually severe for this season of the year.

Sierra.

BALD MOUNTAIN EXTENSION.—Mountain Messenger, April 17: The Bald Mountain Extension Co. cleaned up Sunday 180 ozs., averaging \$2 60 per carload. The main tunnel, being run for the extension of the pay lead, is over 630 ft in the lava flow.

A GRAND DISCOVERY.—North San Juan Times, April 15: A new quartz location has been made by Harry Buhning and others near this place, which promises to become a good paying institution. The location is at a point where the American Company's tail sluices empty into the Yuba river below Sebastopol and within a mile and a half of this place. Rock taken from the ledge shows free gold, and is estimated by experts to assay \$100 to the ton. It appears that the flood, which was created by the breaking of the Milton dam, uncovered the ledge, and that but a few days ago it was discovered by a party who stumbled upon it. Where discovered, the ledge is about six inches wide between the walls, which are slate formation. The ledge runs northeast and southwest and can be traced for miles in Yuba and Nevada counties. Twenty-five locations have been made upon the ledge in the county alone. Our people are much elated with the prospect of having near this place a first-class quartz mine that will give employment to hundreds of workmen. Other quartz ledges will undoubtedly be discovered in this neighborhood in the near future, that will turn out bonanzas.

ANOTHER MINE TO BE OPENED.—Transcript, April 15: Supplies are being sent up to the Norway and Centennial quartz mines (under the same ownership) adjoining and situated in Eureka township, seven miles above the town of Washington and the work of developing those properties will begin next Wednesday by a force of six or seven men who will go from this city Tuesday under charge of David Ayres who has a contract for furnishing the labor. There is on the property a five-stamp mill run by water obtained from the North Bloomfield Company's ditch. The ledges are to be opened by tunnels which will give 2,000 ft of backs. The Norway has a small ledge that has never paid less than \$30 a ton, while in the Centennial the deposits are very extensive and average from \$8 to \$10 a ton.

Siskiyou.

HYDRAULIC.—Yreka Union, April 11: Mr. Wm. P. Bennett is running his extensive hydraulic claim vigorously, and expects to open the best, or one of the best mines ever opened on the Salmon. McNeal & McLaughlin are also working their valuable hydraulic mine. This mine has a splendid water privilege, a thing most necessary to the success of the hydraulic mines. Judging from past experience, this mine is paying well. H. Grant is also pipping away at his claim. This is also a good claim.

NEVADA.

Washoe District.

SIERRA NEVADA.—Virginia Enterprise, April 16: Crosscut No. 1 west, on the 3100 level, 80 ft north of the joint Union Con. winze, is out 16 ft, and is still showing some ore of low grade. Two-thirds of the width of the drift was in quartz for several ft in the start. This quartz contained much good ore, but all being taken out together across the whole width of the drift, it would not pay to mill. The face of the drift was beginning to show a considerable amount of water, therefore the diamond drill has been put in to feel ahead. At a point 123 ft north of

this crosscut they were yesterday cutting out for crosscut No. 2, and in cutting out were exposing some ore. The diamond drill was put in for a considerable distance at the face of the main northeast drift. It showed no water in that direction, and the material brought out—so far as could be judged—was about the same as that which had been exposed in the drift. Good progress, is making in the work of repairing and retimbering the winze between the 2300 and 2400 levels. It will be completed next week. In places it was almost closed, and the work done has already greatly improved the circulation of air in that part of the mine.

GOULD AND CURRY.—On the 2700 level the usual progress is making in the joint Best and Belcher east drift. The drift is in fair working ground, but is very hot. The north drift from the Bonner shaft on the 1200 level is just approaching the south line of the Con. Virginia. At this point it will be taken by J. P. Jones and others, who will proceed to mine the California and Con. Virginia upper levels for low grade ore.

ALTA.—The east drift on the 2150 level is now in the belt of trachyte which lies in front of the ore vein. This rock is very hard, yet fair progress in it is being made. The west drift on the same level is out over 1800 ft. No sign of a west wall has yet been found. The material is still a mixture of quartz, clay and porphyry, some of the quartz carrying metal. The water is being handled without any trouble.

HALE AND NORCROSS.—Are putting in drains and switch plates, and doing other necessary work on the south drift on the 2800 level connecting with the west drift from the Combination shaft. However, this preparatory work is about finished, and the running of exploring drifts and crosscuts will be next in order.

SAVAGE.—There is not much change in the flow of water from the north drift on the 2600 level. Now that connection has been made with the Combination shaft, on the 2800 level, the work of prospecting may be economically resumed.

YELLOW JACKET.—Sufficient ore is being regularly extracted from the old upper levels to keep the mills on the Carson river running to their full capacity. The quality of the ore remains about the same.

CHOLLAR.—The main west drift from the Combination shaft is being extended through the Chollar ground for prospecting purposes. As it is advanced it will be gradually turned to the southward.

UTAH.—The north drift on the 1950 level has been extended 33 ft. The face is in vein material, showing quartz, porphyry and clay. The ground continues quite dry and works well.

CROWN POINT.—Ore sufficient to keep the mills going to their full capacity is being regularly extracted, and the exploring drifts have exposed much more ore than that will pay for milling.

CALIFORNIA.—The east drift on the 2900 level, joint with Con. Virginia, is being pushed as rapidly as possible in ground that works very well.

CON. VIRGINIA.—The joint California east drift, on the 2900 level, is being advanced at the rate of nearly 30 ft per week.

MEXICAN.—The winze on the 3100 level is down 20 ft. It is still in about the same material as that in which it started.

UNION SHAFT.—The upraise to the drain drift on the 1600 level, leading out to the Sutro tunnel, are still continued.

BELCHER.—The several drifts on the old upper levels continue to yield well, and the mills are all kept going.

ANDES.—The usual prospecting work is being done, and some ore is being taken out that will pay for milling.

OPHUR.—Ore is still being extracted on the 150 and 250 levels.

Belmont District.

BELMONT.—Courier, April 19: On Monday last we visited the 200 south level of the Belmont mine. There is considerable rich chloride and black metal ore exposed in this portion of the mine. The ledge averages four ft in width, and the work of development is being pushed as rapidly as possible. The level continues in good ore and the prospects never have been more favorable than they are at present since work was commenced on it. In order to facilitate operations under ground, they have hoisted several tons of ore to the surface. Asa B. Eastwood, the Supt., *pro tem.*, informs us that it is the intention of the company to thoroughly prospect this portion of the mine—it being entirely virgin ground—and that he expects to extract many tons of high grade ore between now and summer.

Bristol District.

DAY.—Pioche Record, April 12: Some 75 tons of ore from the late strike on the Day mine has reached the furnace, and it is fully as good as we have heard it represented. The ore is a copper-colored carbonate, with rich chloride of silver all through it, and is unquestionably the best lot of rock we have seen come from the bowels of mother nature in a long while.

Columbus District.

MOUNT DIABLO.—True Fissure, April 19: The west drift near the Callison winze, on the second level, now shows a total length of 107 ft, and has some promising spots of low grade ore. The south crosscut from the east drift, on the second level, has been driven 21 ft and has passed through a small streak of ore about 4 inches in width, assaying about \$50 per ton. On the intermediate, between the first and second levels, the east drift has been run 11 ft. Its face is showing eight inches of \$90 ore. A distance of 12 ft has been made in running the west drift on the first level without developing any change in the formation of the ground. The sinking of the incline has encountered some very hard ground, only 11 ft of headway having been made during the week. It is now down a total distance of 73 ft below the third level.

COLUMBUS CON.—The fourth level crosscut was extended 10 ft during the week, making a total length of about 85 ft. The material in the face continues about the same as when last reported. The work of extending the main drift on the third level was discontinued. Its present length is about 250 ft. The west drift from the main drift on the third level has attained a length of 75 ft, and the face of the same is in broken vein matter. Crosscut No. 1, on the same level, has attained a length of 35 ft.

The same is being run through ground that looks Eureka District.

LOCAL NOTES.—Sentinel, April 15: The Helen Mortimer, held under lease by Judge Doolin, Jerry McMahon and Dennis Crowley, shows lots of ore and a prospect for a big mine. The ore taken out by the lessors runs from \$50 to \$100 and averages \$80 per ton all through. This mine is said to have the best defined vein in the district. It adjoins the California on the south, which is another fine property. The Hamburg tributaries are all in bonanza. Two of them have over 100 tons out. The Connolly is opening out well. Joe Molino and Alex. Fraser have it rich in the Altoona.

Ellsworth District.

THE MOUNT VERNON.—Belmont Courier, April 19: We understand that the owners of the Mount Vernon mining property at Ellsworth, this county, will, in the near future, resume operations on the Mount Vernon mine. Enough money has been raised East to work the mine in a systematic manner. We are glad to know this, for the reason that persons who have a thorough knowledge of the property believe the Mount Vernon is a good mine. The company has already expended \$70,000 on this property, and considerable work has been performed upon it. The main shaft has been sunk to a depth of 159 ft, and it has a capacity of 7x9 in the clear. The tunnel has been extended 700 ft, and the tunnel level has been prospected for a distance of 300 ft on the course of the lodes. About 66 ft below the tunnel they have intersected the Kohinoor ledge, and have crosscut 200 ft toward the Alhambra lodes. The company has a tunnel right of 3,000 ft. Captain Robert Knapp, the Supt., firmly believes that by sinking 100 ft more they will encounter a good body of paying ore. We wish the owners of the Mount Vernon success.

Gillis Mountain District.

HIDDEN TREASURE.—Esmeralda Herald, April 12: J. B. Hiskey, surveyor, has returned from Gillis Mountain mining district, where he went to survey the Hidden Treasure and Yellow Jacket mines. From him we learn that the Hidden Treasure is the mine out of which ex-Sheriff Clem Ogg and his partners took so much money. The present company have an incline 160 ft down on the dip of the vein, which is about 20 degrees, from which several drifts have been run all the way in fine ore of high grade. Ten miners are at work on this mine extracting ore to be shipped to Dayton for reduction. Certainly in the near future some company will erect reduction works in the vicinity of Luning for the reduction of the rich silver and copper ores there—by saving the cost of transportation and exorbitant percentages exacted from shippers and furnishing means of reducing ores of a grade that cannot be sent away for reduction, but would pay the owners some profit if worked here. And it would also give employment to many men and teams, and be of general satisfaction to this community.

Very favorable for ore. The west drift from the winze on the adit level has attained a length of 25 ft, and the ore in the same continues as last reported. A drift has been started to the east from the same point, following a seam of good grade ore. Crosscut No. 3, from the main drift on the 150-foot level has been started, and it is being run through ground that is favorable for ore.

Pioche District.

TO RESUME.—Pioche Record, April 12: Work will be resumed by the Bullionville Smelting Co. this summer, and we learn from Salt Lake that the works for working tailings will at once be placed in order. It was out of the tailings at Bullionville that the company managed to get the money to work their mines at Frisco, Utah, and as soon as they closed down at Bullionville they were shortly compelled to close the company's works at Utah.

Reveille District.

BACKWARD.—Belmont Courier, April 19: From C. A. Ogden, who arrived in Belmont on Monday from Reveille, we learn that the cold weather has greatly retarded mining operations in that district. Jos. Bianchi & Co. have received nearly all of their leaching materials, and it is expected that the balance will soon be hauled in from the railroad. The Norris Brothers have several good prospects at Reveille and they believe that they will make a good showing next summer. There are a number of prospectors who will resume work as soon as the weather permits. The striking of paying mines at Reveille is not improbable.

SILVER LICK.—Sentinel, April 18: This mine, from which large quantities of ore have been extracted at different times in the history of the camp, has recently sprung into new life, and is now yielding better ore and more of it than ever before. The property is in charge of Supt. J. C. Powell, who has leased it to tributers. There are six of these who are making their "pile" out of it. The boys will soon be getting coin for their rock. It is encouraging to know that there are a score of other mines in the neighborhood which show up as well as the Silver Lick does. It looks as though the old camp will be in bonanza all along the line this summer.

Tuscarora District.

HYDRAULIC MINING IN TUSCARORA.—Times Review, April 14: A company of Chinamen are rigging a hydraulic apparatus for gold washing at Eureka ravine. They have sent to San Francisco for several hundred ft of hose and intend to put in about a thousand ft of flume. This will be the first attempt at hydraulic mining in this district. Several other Chinese companies are setting sluices for placer mining Gardner, Canton and Halfmoon ravines. The water supply this season is more plentiful than ever before, and the Mongolians expect to be able to continue work a month later than usual. All of the companies get their water from the ditch which they have leased from the Beard Bros.

DRAINING THE MODOC.—The Beard Bros. are rigging a hand force pump with which to drain the Modoc mine. The incline is down 90 ft and the water has risen to within 20 ft of the top. They think their pump will drain the mine to a depth of 150 ft. The ledge at the bottom of the incline is upwards of seven ft in width with quite a number of streaks of rich ore. It has greatly improved in appearance in the last ten ft and the owners feel correspondingly encouraged over the prospect.

CENTRAL CON.—East drift, old workings, extended 25 ft; assays from face \$18.50 to \$25.00 in the west drift, are stopping out some fair grade ore.

INDEPENDENCE.—During the past week the usual

progress has been made in the west crosscut and upraise on the 300 level.

NAYAGO.—Work in and about the mine progressing as usual. The mill has crushed the usual amount and grade of ore. Shipped \$8,225.00 last Monday.

NORTH BELLER ISLE.—Have commenced cleaning out crosscut No. 2, 350 level, preparatory to resume work in the same. Have let a contract on 70 level, to run a drift north.

BELLER ISLE.—Winze No. 1, 350 level has been sunk six ft during the past week. Have put blowers and pipe on 450 level, and started a crosscut to connect with winze No. 1.

ARIZONA.

MOHAVE.—*Miner*, April 15: Supt. Fisher of the Schuyllkill mine tell us that the new shaft is down 75 ft with eight inches of good ore in the bottom. Fred Buer has sold one-half interest in the Last Salvation claim to John T. Davis of Hackberry. This claim is in the Music mountain district. The heavy rains of the past week will again retard mining operations in this district for some time to come. The well at the Corbat mill is full to overflowing. A constant stream of water has been running from it for weeks. Messrs. Cole and Caffrey of the Alpha mine were in town last Sunday. They recently shipped nine tons of ore from this mine which netted them \$900. The ore was shipped without much sorting as a sample lot, and the boys are very well pleased with the returns. They are good workers and deserve to succeed. Louis Davidson has sold three-fourths interest in the following mines, viz: Oro Fino, Great Western, Great Eastern, Boss No. 2, and Alvoid mines to L. Simmer, for one silver dollar. A. B. Warner has sold his interest in the Alpha, Warner and Standard claims to Ed. F. Thompson for \$250. A deed from J. E. Hollenbeck of Los Angeles to M. Salsbury of San Francisco conveyed the Schenectady and Schuyllkill mines at Chloride has been placed on record. The consideration expressed in the deed is \$3,000. Jett, having disposed of one-half of the Buster claim in Maynard district to T. L. Ayres and the other half to J. K. Mackenzie. Two lots of ore shipped by B. Fredericks from the new Groom's Peak district to the Hackberry mill sampled as follows: Lot F, three tons, 147 ounces silver per ton, lot K, one and a half tons, 345 ounces per ton. The ore was sold to John Howell on the basis of 90 per cent of the market value of the silver, less milling charges. There is no ore in the Quijotoa, Coeur d'Alene, or any other of the much-boomed districts that will average any better than this.

BONANZA MINES.—*Quijotoa Prospector*, April 12: There is nothing special to report this week. Work is progressing in a very satisfactory manner in all the tunnels, which are daily drawing nearer the vein. Owing to a miscalculation in the measuring, some ninety ft more than first supposed will have to be run in all the tunnels. This error occurred by believing that a vertical line drawn from the top of the mountain would strike the mouth of the tunnels, but it was found that such was not the case, there being a difference of about ninety ft between the points mentioned.

PERKLESS.—Tunnel No. 1, east side, is cutting about the same kind of ground it was last week. On Wednesday it measured 134 ft.

WINZE.—The winze was down 64 ft on the 9th inst. in high grade ore, which has materially improved since the last report.

HORSE MOUTH.—The crosscut on the vein at this point was on Wednesday last 30 ft in length. It showed indications that the wall was near. It is quite probable that a drift will be started to the south on the vein some time this week. The 30-foot crosscut is in good milling ore.

SHEEP NESE.—Nixon Palmer, Supt. of this property, arrived in town last Friday evening from San Francisco, but owing to his absence on Wednesday last the mining reporter was unable to see him and learn the intentions of the company. Work on the tunnel is being pushed with customary vigor through the same quality of ore.

In looking over the mining news of Mohave county I seldom see any mention made of "Chloride," that rich old mining camp just north of Mineral Park; yet many of the best mines in Mohave county are situated in Chloride, and more high grade ore is shipped from that section than from any other camp in the great Wallapai district. The "Pink Eye" mine, of Chloride, is one of the very best mines of Mohave county. When I last saw the mine, the shaft sunk on the hanging wall was 70 feet deep. A cross cut, drove from the bottom of this shaft, 13 ft, cut through a large ore body that assayed over \$70 in silver, per ton. Drifts running north and south on the ledge, 30 feet below the surface, showed a fine, strong vein of rich chloride and gray carbonate ore. The flow of water in the mine prevented the owners from sinking the shaft deeper.

GALIARA AND BUNKER.—*Tombstone Epitaph*, April 12: From Ed. Clark, who has recently returned from the Galiera and Bunker Hill districts, it is learned that work on the Jackson claims, in the former district, is being prosecuted with good results. Two shafts about sixty ft in depth each, have been sunk, the bottom of each showing good ore. On the Jennings claim an ore body assaying about \$400 per ton has recently been struck. The Tweed copper claims, on the Gila, will soon have a large force of men put to work on them. A claim known as the Morning Flower, in Bunker Hill district, is being worked by a man named Hinditer, and some exceedingly rich ore taken out. Samples brought in by Mr. Clark will assay into the thousands.

TURKEY CREEK DISTRICT.—*Cor. Prescott Courier*, April 12: A big strike in the Roach mine is the only excitement in camp. The boys have struck over a foot of ore in the shaft that will assay up into the hundreds. The Chase company are going steadily ahead, pushing work on the mines and mill. Seeing no prospect of the road being repaired between here and Prescott, the company have concluded to have their machinery hauled in by way of Big Bug. For this purpose they have put a force of men to work repairing the old Bully Bueno road.

PROSPECTS AT QUIJOTOA.—*Prospector*, April 19: Every successful mining camp goes through three stages of existence. First, there is the discovery, and a grand rush from all parts of the coast. Men with every sort of object in view, and with no object at all, flock to the new El Dorado, to make a for-

tune. The second stage is the reaction from the first. Every description of business is overdone, real estate has been driven up to Broadway prices, and folks had that twenty-dollar pieces are not much more plentiful on the bushes here than elsewhere. Discouragement causes many to leave. Then comes the third stage, when work in earnest has been commenced on the mines, money is being disbursed regularly, and all legitimate business is brisk and remunerative. Our camp is at present passing through the second of these stages. Because the Bonanza mountain has not been cut through like a piece of cheese, and the riches it contains reduced at once into bullion, some folks, who have had little experience in mining camps, are becoming anxious about the future, and take a gloomy view of things generally. Such ideas are very unreasonable. It takes time to bore into a solid mountain. Work is being pushed as fast as unlimited means and skill can do it. This is, however, not like a placer camp, where every man can take out three or four dollars a day and place a large amount in circulation. The mining outlook is better here than it has ever been, and those long-headed persons who are evincing their faith in the future by putting up solid improvements, will, in a few months, reap the reward of their enterprise.

SPICER DISTRICT.—*Quijotoa Prospector*, April 19: The Spicer district, which covers the Mica Lake range, about 17 miles distant from Quijotoa, is attracting considerable attention. Among the most promising properties located there are the Spicer claim, Silver Jim, Louisa Byron, Hidden Treasure and the Mahar. From the latter claim ore assaying \$500 to the ton is being shipped. A shaft is now being sunk on the Silver Jim, which assays \$250 per ton. Several mining men who have visited that section say that it has a bright future.

COLORADO.

A GOLD EXCITEMENT.—A dispatch from Denver, dated the 20th, says: Intense excitement prevails throughout Colorado over the recent rich discoveries of gold on West Oil and Cottonwood creeks, near Canon City, in this State. Mining men are working themselves into fever heat, and although the rich quartz was found only a few days ago, already there are hundreds of fortune hunters on the way to the new diggings. The first discovery of gold was made by a man named Teller, on a ranch owned by John O'Brien. The ranch was prospected many years ago, but it is thought that the coating of the gold or its being in chloride form held in magnetic iron and covered with oxide of tellurium, prevented it from showing in the pan, and nobody thought of making scarification or erubile test. Several assays already made run from 10 to 100 ozs. in gold, with a probable average of 35 ozs. At first many were inclined to believe that the excitement was gotten up by some of the railroads, as an offset to the Coeur d'Alene mines, but little doubt is felt now that the strikes are genuine, and that they will result in giving another impetus to this State. From all parts of the country miners are flocking to the diggings, confident of finding the much-desired wealth.

WHITE PINE.—*Cone*, April 12: Work is progressing steadily on the Valhalla tunnel. The day shift is making from six to eight inches a day. Penney and Claypool are working their Horse Shoe property, the Ella Rhoat. They have a fine carbonate lead. Howard Pierce has the Sedalia down over 100 ft, and is pushing the work right along. He will have a pay mine there before he quits. If Judge Gerry dissolves the injunction to-day, we understand the Eureka people will put on from 75 to 100 men, and make things hum on the hill. It has been rumored this week that the North Star would resume work next Monday. We have been unable to see any of the managers, but trust the report is true. The Star is too good a mine to remain long idle. E. M. Paine and Hopkins brothers have taken a contract to sink and timber 30 ft on the Paymaster, and 20 ft on the Nimrod, for a third interest in both claims. The contract was secured from Ed. Kenyon and Robert Smith. The claims are located near the Silver Trowel, and the owners think they will have pay ore by the time the contract work is completed. If not they will continue work until they do find it.

NOTES.—*Register-Call*, April 18: George Ebert and Richard Jenkins, who are working the Wyoming ledge, over on Fall river, sent a run of ore to the mills at Georgetown a few days ago, for which returns gave 110 ounces of silver and four per cent of copper for first-class, and fifty-two ounces silver and one and one-half per cent of copper for second-class. When taken into consideration that the above ore came from a depth of only 30 feet, the richness of the vein shows it to be much better than the average. Stratton, Eads & Breton, lessees of the Main mine, who have been doing dead work from the main shaft on that vein, in raising from the workings on the same through the German tunnel, have made connection, and as soon as the proper stulls can be put in will commence breaking ore, the ore body in sight covering a block fully 200 feet as passed through in sinking and raising. A reporter of the *Register-Call* yesterday afternoon observed a load of ore amounting to about three tons pass through the city from the Silver Plate mine, which is located under the northerly wing of Bald mountain. The First National Bank shipped \$8,200 in gold bullion to the Denver mint yesterday.

NEVADAVILLE DITS.—A Nevada correspondent contributes the following local dots from that place: The Ute mine owned by D. H. Andrews, H. J. Hawley and J. S. D. Manville, have everything in smooth working order about that property. The main shaft is being sunk by three 8-hour shifts of miners. This vein will soon be in condition to turn out a large amount of milling and smelting ore. The First National Bank company's property on the Burroughs lode, recently leased to Captain Noonan and others, and which has been idle for five or six years, is being developed by sinking the main shaft. The lessees have erected a new and commodious shaft house, and have a plant of machinery of sufficient capacity to sink the main shaft to a depth of 1,200 feet. A contract was let last week for sinking an additional 75 feet. The outlook in the lower workings is very encouraging. In past years this portion of the Burroughs paid largely for working. McFarlane Bros., contractors, have a force of mechanics at work erecting a new shaft building over the main shaft on the Hubert mine.

The machinery formerly used on the Forks mine is being removed and will be placed in the building. Mr. Henry B. Singer, the superintendent, has miners at work enlarging the shaft and making other necessary underground improvements.

IDAHO.

NEW GOLD FIELD.—*Bellevue Chronicle*, April 15: E. J. Smiley, of Resurrection district, 12 miles below Bellevue, was up yesterday with some fine specimens of gold ore from a new strike in the Smokestack and Orient. This ore ranges in value from \$30 to \$200 per ton, and is a little ahead of any yet discovered there. The Smokestack joins Hailey & Smith's Susie S. on the west, and the ledge is as wide as that of the Susie. Mr. Smiley has been at work there all winter and is much elated over the success of his labor. Hon. John Hailey contemplates erecting a re-stamp gold mill there the coming summer, and will soon have a force taking ore from the Susie S. Col. Canavan and Gen. Schenck, of Bellevue, also own some gold mining property in the district and propose to begin work soon. Col. Canavan took samples of the new strike, in which free gold was plainly visible, to Boise City with him, and will interview Hon. John Hailey concerning the mill project for the new district.

THE MAYFLOWER VEIN.—*Wood River Times*, April 12: After nearly two years of active search, the continuation of the Mayflower vein has been found, at a depth of about 200 ft below the old ore stopes, and at a point about 200 ft westerly of where it should have been. Those familiar with the facts will remember that in the workings from the lower Mayflower tunnel level, the vein was entirely lost after a depth of 50 or 60 ft had been gained by the prospecting winzes, and this caused well-founded alarm for the future, not only of Bullion, but of all the Wood river mines, as it was argued that if the Mayflower vein did not go down in depth there was no likelihood of any of our veins going down. The re-discovery of the Mayflower vein will, therefore, have a tendency to strengthen the confidence of owners and investors in our mines. It will be interesting, in this connection, to note the developments of the vein, to ascertain if it maintains its ore-bearing character.

COEUR D'ALENE.—*Cor. Inter-Mountain*, April 16: I have just seen the world wide Mother lode. It is a big boulder of quartzite on the edge of the creek under an overhanging mountain of slate. It is without pitch, shape, strike, wall or anything that goes to constitute a true fissure and the area of exposure is only about 5x10 ft. Next to what passes to the hanging wall is a very pretty display of gold spattered over the quartz but it does not appear how deep it sinks into the rock. Otherwise the chunk of quartzite is barren to all appearances. It is owned by two old men, and two good miners in ten hours could do more work than has yet been done on the property. The old fellows stand in the waters of Prichard creeks up to their waists, while eager visitors almost swim to get a glimpse of the fabled treasure. They will have to swim in dead earnest when the creek rises another foot. This mother lode is the only thing in the quartz line worth speaking of in this whole region as far as my observations have extended. I have not yet seen any specimens around here that a Montana prospector would tolerate around his cabin. Notwithstanding all this the country is big enough to contain good quartz camps and they may be struck yet, but as far as this excitement is concerned it is a miserable fraud. All classes of business men are sick and disgusted as everything is overdone. Provisions are cheaper than formerly, but wages are low. A very few weeks now will tell the tale.

COPPER.—*Wood River Times*, April 16: A report has been current in town during the past few days, to the effect that the famous group of copper mines in the Lost River country had been sold to English capitalists; but a *Times* reporter found upon investigation, that there was no foundation for the report other than the fact that the owners had had refused to consider a proposition to sell outright for over half a million dollars cash, or to bond the property for \$800,000. The group of mines referred to consist of five claims named, respectively, Old Judge, Copper King, Buena Vista, Golden Wave, and Henrietta. They are located in a range of mountains lying westerly from Lost River valley, and about half-way up the valley. The vein—if vein there be—has massive outcroppings 800 ft wide, and the total length of the vein covered by the locations is 3,500 ft. In this ground some 15 or 20 shafts and several cuts have been made. The greatest depth of any shaft is 60 ft; greatest length of any cut, 40 ft. But all of both cuts and shafts show solid ore on all sides that ranges from 20 to 50 per cent in copper, and from a few ounces to several hundred ounces in silver. The average of a large number of assays made in this region, in Salt Lake, in Denver, in Omaha, in San Francisco, and in New York City is 41 per cent copper and 75 ounces silver, or a value of about \$197 per ton. These assays while not made from selected ore, were, however, made from brown and black oxide and sulphurets ore which are undoubtedly above the average run of ores in the claims. But they were undoubtedly fair average samples of one portion of the vein from which thousands of tons, at least, can be taken. These claims are owned by Frank Brown, the Bruners, and G. A. Williams, a well-known attorney, who propose to develop them, as they say that the property is too vast and evidently too valuable to permit even an approximate idea of its worth being formed. They have men working on the claims now; but as soon as the roads are open they will put on a heavy force of men and will doubtless, before the season is over, have two or three of the matting furnaces of the Pacific Iron Works turning out matte by the car-load. It is no wonder that the owners of this property are unwilling to sell. If half of what is reported about it is true they have the most gigantic deposit of ore ever found in the world. Such is its width that mining men will not, until the contrary shall have been demonstrated, believe that the 800 ft claimed for the width of the vein is anything but a blow out or horizontal deposit caused by some convulsion of nature.

MONTANA.

NEW SMELTER.—The Parrot Co. will build a new smelter. Timbers are being framed, excavations are going on, and the whole work will be completed by the fall. New smelter will concentrate 150 tons of

ore per day and be furnished with one blast furnace of a capacity of 75 tons to 80 tons every 24 hours. Copper bullion instead of matte will be shipped from the new works. The present works are producing 750,000 pounds of pure copper per month, or 25,000 pounds a day. Reckoning this copper at 14 cents a pound, it will be seen that the daily output of this smelter alone amounts to \$3,500, or \$105,000 a month. Dr. Peters informed the reporter that there was but one smelter in the United States, the Calumet and Hecla of Lake Superior, that surpasses the Parrot in its output of the metal. The works concentrate about 100 tons of ore daily and run 80 to 85 tons into matte. When the new smelter is completed the company will purchase ores at reasonable rates thus enabling owners of copper mines, now laying idle, to realize upon their properties. The new works will be built a few rods southwest of the present ones. The narrow-gauge railroad running from these works to the mines, will be completed within the next ten days. The grading is all done and truck lading is progressing satisfactorily.

THE ANACONDA.—This vast property, whose productive capacity is perhaps greater than that of any other copper mine in the world, continues to be developed with the regularity and system of clock-work, though the policy of the management as to the publication of news concerning its operation is extremely conservative. From a reliable source it is learned that between the 200 and 800 levels, inclusive, 14 lifts are being extended, seven east and seven west. The face of each of these drifts is in solid ore and has been from the several crosscuts. There is no mine in the western territories in which operations are conducted on such a scale, nor in which the ore occurs with such uniform regularity with respect to richness and extent. The product of the mine is made up entirely of the ore necessarily extracted in extending the drifts. Yet the output amount to thousands of tons monthly, of which 2,500 tons assaying upwards of 50 per cent copper, are shipped in a crude state to Swansea. The dump is assuming gigantic proportions and must now contain in the neighborhood of 175,000 tons of low grade ore, susceptible however of profitable treatment. The company is working over 300 men in and about the mine.

THE BELL.—*Inter-Mountain*, April 18: The Bell smelter is now treating daily 30 tons of ore in one of its blast furnaces and is producing eight tons of matte, which is sent regularly to Swansea. It assays over 50 per cent copper and contains more silver than any other matte produced in Butte, except that of the Colorado smelter. The concentrator to be run in connection with the smelter will be started up on Monday, and as a result, the matte will be of much better quality than heretofore. About fifty men are employed at the works. The condition of the mine is quite satisfactory. The 400 foot level is now yielding about 30 tons of ore daily from the faces and stopes. In the west drift, the ore was of low grade until recently, but a large body of a much better quality has been struck this week. It assays well and seems to be permanent.

NEW MEXICO.

ORGAN.—*Cor. Rio Grande Republican*, April 18: The crusher started up again last Tuesday. It is running on copper ore from the Memphis mine, Jenkins and Robinson are doing well on the Little Buck. They are taking out large quantities of high-grade ore. The boys must study up in mineralogy, or they will get left. Some of them were caught throwing away rock that averaged \$200 a ton. Henry Willman has taken out about fifteen tons of very rich ore. The vein is three ft wide, and his prospect looks very favorable for a good mine. The smelter machinery has not yet arrived, though it is looked for daily. When it does arrive, Mr. Roney calculates to have it up in thirty-six hours. They are still sinking on the main shaft of the Galloway, and timbering it up for permanent work. They intend sinking it 200 ft at least this summer. The view from Col. Crawford's camp, near the Galloway mine, looking in the direction of San Augustin Peak, is one of the loveliest that nature can afford. No work is being done on any claim between the Memphis and Little Buck, that we can hear of. All attention seems to be drawn to the San Augustin Peak district. The Thinnerholt, belonging to Foy Bros. and Hoopes, shows fine indications for a good mine, but it has not been opened up much yet. The ore is about the same as all that is found in that district. The Little Chloride is down six or eight ft in gray copper and chlorides, with some sulphurets. It assays \$420 in silver, and 20 per cent copper. It is owned by Crouch and Metcalf, and work on it is being pushed. J. S. Jarnigan has found a new lead near Henry Willman's claim. Chlorides and sulphurets running high in silver. Now that he has found good ore, there are several parties rushing forward to claim a prior location. The Yellow Jacket and El Moro are two claims near the Pass. The latter is yielding nice looking ore. The former has had very little work done on it, but it promises well. Both belong to Hufford, Purdy and Metcalf. The Climax, owned by Metcalf, Purdy and Hertzog, shows up sulphurets and galena assaying \$400. It is a cut of 20 to 25 ft long which strikes a vein from two to three and a half ft wide, between syenite and porphyry, and looks as if it would make a fine lead. From the north shaft of the Galloway they are taking out chloride of silver, slightly mixed with galena and probably some iron, making a mineral of a pretty red and green color, which runs from 1,000 to 1,500 ozs. in silver to the ton. All of it is very carefully sacked for shipment, and over \$7,000 worth has already been taken out. The shaft is 15 to 20 ft deep, and the vein lies between porphyry and granite, with a foot of ore, every ounce of which will pay to ship.

UTAH.

SAMPSON MINE.—*Park Record*, April 19: Mr. Pierson presented us a piece of ore from this mine (out of the new shaft) that seems to be exceedingly rich, and says they have over three ft of splendid pay ore in a vein twenty ft wide between porphyry and quartzite walls. The balance of the gangue between walls is a brown oxidized quartz carrying considerable mineral and a material that would prove an excellent flux in smelting the ore. With a new invention of furnace to be introduced by Dr. Brawer, these and the Crescent ores will flux themselves.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shop and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Branton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Giant and Old Abe Co., Black also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

WORTHINGTON MINE PUMP.

ALEXANDER L. HOLLEY, being duly sworn, says: I am by profession a civil and mechanical engineer. I have been especially employed during the last ten years constructing and managing works for the manufacture of Bessemer steel. I am now Consulting Engineer to the Bessemer Steel Works of Troy, the Cambria Iron Works, the Bethlehem Iron Works, the North Chicago Rolling Mill, the Joliet Iron and Steel Works, and the Edgar Thomas Steel Works. In all Bessemer Works the hydraulic machinery is the most expensive and the hardest worked part of the plant. Any delay or serious fluctuation in its operation is fatal to the commercial success of the Bessemer process. After extensive acquaintance with the **WORTHINGTON ENGINES**, and with all such other forms of pumping engines as have been applied to the purposes required, I have adopted it exclusively, and to my knowledge it is adopted in every Bessemer works running or building in America. I have also, for the same reasons, adopted the **WORTHINGTON PUMPS** for feeding boilers.

Will contract to raise any required height single lift with our NEW PATENT MINE PUMP. Recent practical tests in Deep Mines of Mexico demonstrate this to be the BEST MINING PUMP extant. **BRANCH HOUSE**, 30 and 32 First St., S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & Co. in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

AIR AND DUST SEPARATOR.—John P. Anderson, S. F., assignor of one-half to Spivalo and Forman. This machine is specially useful in connection with the dust chambers or the purifiers of flour mills. In the separation of fine dust in flour mills, suction fans or blowers are used, and the dust drawn out by the fans is forced into a dust chamber. To continue the operation it is necessary to have a chimney, through which the current of air can escape, and up this more or less dust goes, causing a nuisance in the neighborhood. To overcome this, a circular hole is cut by this inventor in the side of the chimney, just above the dust chamber, and a small propeller shaped fan is put in. This wheel or fan is just fitted to turn in the tube. The chimney is closed above the wheel and the current of air which escapes from the surplus within the dust chamber strikes against the vanes in passing through the wheel, and causes the latter to rotate rapidly. The effect of this appears to be to cause a reactionary current, which changes the direction of the dust particles and deflects them back within the chimney, so that they settle within the dust chamber, while the air passes out through the spaces between the inclined vanes of the wheel clear and free from dust.

OVERALLS.—Wm. A. Dawson, Stony Point, Sonoma Co., Cal. No. 295,619. Dated March 25, 1884. The object of this invention is to make the pants and overalls more durable by re-enforcing those parts upon which the greatest amount of strain and wear comes. In the corners of the pockets a peculiar coiled stitch is made. This is commenced by running a circular stitch across the main seam at each corner of the pockets and then decreasing the ends towards the center. Instead of lining the pants throughout they are lined only where subjected to the greatest wear. These parts are the front of the leg, the seat and the crotch. Two pockets are made on each side of the back by first forming a large pocket and then running a line of stitches down the center. An extra seat piece is put in also, and the waist-band is peculiarly made.

ROTARY PUMP.—John M. Wiles, Butte City, Colusa county, Cal. No. 295,704. Dated March 25, 1884. It consists of an exterior case with inlet and discharge passages, an interior cylindrical drum revolving on an axis, which is placed eccentric to the outer case, and slotted to receive buckets, and a loose elastic ring which is placed within the drum and the inner edges of the buckets, against which it presses and holds them out to the inner face of the case.

GRAIN SEPARATOR.—Pontalia L. Nash, Hollister, No. 295,668. Dated March 25, 1884. The improvements covered by this patent mainly consist of certain details of construction difficult of intelligent description without the aid of engravings.

New Incorporations.

The following company has been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

LITTLE GRANT M. Co., April 18. Location, Arizona. Capital stock, \$10,000,000. Directors, C. C. Harvey, F. G. Margetson, W. R. Sherwood, Joseph Marks and S. F. Ralston.

ARLIE M. Co., April 18. Location, Arizona. Capital stock, \$10,000,000. Directors, C. C. Harvey, F. G. Margetson, W. R. Sherwood, Joseph Marks and S. F. Ralston.

PIMA M. Co., April 18. Location, Arizona. Capital stock, \$10,000,000. Directors, C. C. Harvey, F. G. Margetson, W. R. Sherwood, Joseph Marks and S. F. Ralston.

IMPORTANT additions are being continually made in Woodward's Gardens. The grove walled with aquaria is constantly receiving up accessions of new fish and other marine life. The number of sections is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

THE Postoffice Department has issued orders establishing new offices in Arizona at Armer, Crittenden, Payson and Quijotoa.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

DUNHAM CARRIGAN & Co. have removed from the old quarters on Front St., where they have been so long, to a fine new building fronting on both Beale and Main Sts.—Nos. 18 and 24 on the latter. The building was specially constructed for the firm, and has been carefully designed to meet their requirements. Dunham, Carrigan & Co. have gradually increased their business to such an extent that removal to more roomy quarters was necessary; and they wisely concluded to build for themselves. The new structure is heavily built, and of fine architectural appearance. As soon as they are thoroughly settled in their new quarters we shall give a more detailed description of the building.

AN EASY BINDER.—A. T. Dewey's Patent Elastic Binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price, size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co.'s journals, Harper's Weekly and Scientific American, 85 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. Send to this office for illustrated circular. Agents wanted.

Intelligent Boy Wanted
To work in a photograph gallery. Satisfactory references required. Fourteen to eighteen years of age preferred. Wages moderate at first. A country lad or one who lives at home in the city preferred. Apply at this office.

JOHNSON'S Horse-power Diagram, \$2; Bourne Steam Engine, 1874, \$3; Hand Book Der Petre Fackenkunde, 2 vols., Atlas of Plates, 1,320 pages, 2,595 illustrations, \$8; Tubingen (Tunnel Building, German Text), Atlas and Text, Gatzschman Freyburg, \$2.50; Elements Analytical Mechanics, by Barlett, \$1.50; Amott's Elements of Physics, \$1.50; and 4,000 other books, at HEALY'S BOOKSTORE, 104 O'Farrell street, S. F.

Mining Share Market.

The stock market continues very dull. Hope long deferred has made many desert the halls of the Stock Board for more profitable occupations. On the Comstock they are still working away hopefully. In the Sierra Nevada the work of exploring the 300 level has been commenced. They are now cutting out for No. 2 crosscut at a point 123 ft north of No. 1. In cutting out some pretty fair ore is being exposed. This is at a point 203 ft north of the joint Union Con. winze. In crosscut No. 1, the greater part of the way, they had on one side a streak of quartz and ore that extended two-thirds of the way across the width of the drift. Where they discontinued, in order to put in the drill, this streak still continued, but was narrower and poorer. At the middle mines they are now getting their drains, tracks, switches, etc., in position on the 2800 level, and are about ready to begin prospecting in good shape. The Chollar folks are pushing the west drift from the Combination through their ground. This drift will be gradually turned south and will form the main line on the level from which to crosscut. They will now also be able to prospect economically in the Savage ground. The leading Gold Hill mines are taking out and shipping to the river mills the usual amount of ore. The indications are that there will be no scarcity of water in the Carson river during the coming summer.

Bullion Shipments.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

Mining Machinery Depot,

PARKE & LACY,

21 and 23 Fremont Street. S. F.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

Displacements in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

Educational.

TRINITY SCHOOL—CHURCH, BOARDING AND Day School for Young Men and Boys, 1534 Mission St., San Francisco. Prepares for College and University. Easter Session opens Thursday, Jan. 4, 1884. Refers to—Wm. F. Babcock, Esq., Col. E. E. Eyre Joseph Downing, Esq., Gen. L. H. Allen, Wm. T. Coleman, Esq., Geo. W. Gibbs, Esq. For information, address, REV. E. B. SPALDING, Rector.

W. E. CHAMBERLAIN, JR.

T. A. ROBINSON.

Returned to new building, former location, 320 Post street, where students have all the advantages of elegant halls, new furniture, first-class facilities and a full corps of experienced teachers. Send for Circulars. LIFE SCHOLARSHIP, \$70.

THE HARMON SEMINARY,

Berkeley, Cal.

A BOARDING AND DAY SCHOOL FOR YOUNG LADIES.

This institution will be continued with the spirit and methods of its founders by those have grown up with them in their educational work. The corps of instructors is full and of recognized excellence in all departments.

Address, THE MRS. HARMON, Berkeley, Cal., Or E. J. WICKSON, 414 Clay St., S. F.

SAN FRANCISCO.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

Put up in 5, 1, 1/2 and 1/4 gallon cans and bbls.

Send for Supplementary Sample Card of Olive Shades to

O. S. ORRICK, General Agent,

403 MARKET ST., SAN FRANCISCO.

Also Sole Agent for the Genuine San Francisco Rubber Paints, and Dealer in OILS and PAINTERS' MATERIALS.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

Manufactured only by

For Sale by
DUNHAM, CARRIGAN & CO., San Francisco, Cal. JENKINS BROS., 71 John St., New York.

Gold Medals for Best Truss in Existence.

The I-X-L ELASTIC TRUSS has

Cured more cases in the short period of its existence than all others combined during the last century. Has the Universal Joint movement in the Pad (ball and socket adjustable), making it the most positive refainer, combining comfort and ease, over all invent- ed, and performs mir- aculous cures where all others fail. Indorsed by the Medical Faculty of the world. This Truss is not a magnetic or electrical humbug, but an intelligent Radical Cure Truss. I-X-L ELASTIC TRUSS CO., Main office, No 646 Market Street, San Francisco, Cal.

First-Class Stationary Engine For Sale.

Right or left hand; 10 1/2x24 inch cylinder; fly wheel 3,500 pounds; nearly new and all in perfect order. Will be sold at a great sacrifice for want of use. Terms of payment easy; on installment plan, if desired. Original cost \$1,200. Can be seen in position any day. Address H. M., box 2361, S. F. P. O.

Analytical Chemist and Assayer.

Analysis made of Ores, Soils, Medicines, Water, Etc.

I have had 10 years' experience in the employment of the Japanese Government, and can guarantee perfectly correct results in work in any of the branches mentioned. DR. G. MARTIN, Care of Mr. Beytuss, 206 Front St., San Francisco.

SPECULATORS AND CAPITALISTS READ THIS!

I know where there are immense deposits of coal, worth millions of dollars. I need from twenty thousand to fifty thousand dollars, or more, to LOCATE, ENTER and IMPROVE said coal lands, much of which is upon Government land. Any person having the money mentioned to invest can make arrangements with the advertiser to go out with him and see with his own eyes the immense quantity and value of said coal lands. I am fully convinced that any party investing in said coal lands can, in less than two years, realize at least one hundred dollars for every dollar invested. Any person possessing the requisite means and meaning "business," can address for two weeks, appointing time and place for interview,

A. B. "COAL."

Care of E. R. Robinson, P. O. box 1474, San Francisco, Cal.

N. B.—The advertiser can show the very highest testimonials concerning integrity and business capacity.

To Architects and Builders.

Valuable Vault for Sale at a Bargain

A contractor has a thoroughly burglar-proof vault for sale. Dimensions, 4 1/2x5 ft.; height, 7 ft. in the clear; weight, about 6,000 lbs. In perfect order throughout. Double doors inside. Single burglar-proof outside door, 1 1/2 inch steel and iron combined. The bolt work is of superior and first-class quality in all respects, there being no better on this coast. Can be examined at any time. Write for further information. Address P. H., box 2361, S. F. P. O., or inquire at this office.

Engraving

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

THE ROLLER ORE FEEDER

Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

Golden State and Miners' Iron Works,

Sole Manufacturers,

237 First Street, SAN FRANCISCO, CAL.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers—\$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver; Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

Iron and Machine Works.

MACBETH'S —PATENT— STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys. They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, NOV. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction. They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),
(Signed) RICHARD T. MARSH,
Managing Director.

HEINE PATENT SAFETY BOILER, RISDON IRON AND LOCOMOTIVE WORKS,

Sole Agents for the Pacific Coast,

Corner Beale and Howard Sts., San Francisco.

Economy in space and fuel. Safety at high
pressures. Freedom from scaling. Equally
adapted for power and heating purposes.
Especially adapted for mills, factories, hotels,
stores or any place where safety is a necessity.
Will work well with muddy water and any kind
of fuel.

TESTIMONIALS.

ST. LOUIS, Mo., Sept. 23, 1883
Messrs. Adolphus Meier & Co.—GENTLEMEN:
We cheerfully certify that the "Heine Patent
Safety Boiler" put up by you in our establish-
ment has proved very satisfactory in its work-
ing. The chief points of excellence in the "Heine
Safety Boiler" are its economy in fuel and space,
freedom from scaling, aptitude for power and
heating purposes, working equally well with clear
and muddy water. We warmly recommend it to
all using steam machinery. Yours truly,
ANHEUSER-BUSCH BREWING ASSN.

OFFICE OF Supt. of ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to
your inquiry of September 24, we respectfully in-
form you that the three boilers built under your
patents, under steam since September 25, 1881, at the Alex-
ander Platz Depot, as well as the two at Friedrich Strasse
Depot, under steam since September 22, 1882, have given
good satisfaction, requiring no repairs whatsoever to date.
The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the
tube caps, the adhesion of scales being fully prevented
thereby, and the boilers kept in prime condition.

(Signed) BRAUCKE.

WATER JACKET SMELTING FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace
many features that are entirely new and of great practical
utility, which are covered by letters patent.

No other furnaces can compare with these for dura-
bility and in capacity for uninterrupted work.
MORE THAN ONE HUNDRED of them are now run-
ning on the Pacific Coast, giving results never before
obtained as regards continuous running, economy of
fuel, grade and quality of bullion produced. We are
prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requir-
ing no brick or stone work, a except that for the crucible,
thus saving great expense and loss of time in construc-
tion.

Complete smelting plants made to order of any capacity
and with all the improvements that experience has sug-
gested as valuable in this class of machinery. Skilled and
experienced smelters furnished when desired to a open
intend construction and running of furnaces. Estimates
given upon application. Send for circular.

CONCENTRATION OF ORES (of all kinds), including the Chlo-
rination Process for Gold-bearing Sulphurets, Arsen-
urets, and Gold and Silver Ores generally, with 120
Lithographic Diagrams. 1887.

This work is unequalled by any other published em-
bracing the subjects treated. Its authority is highly
esteemed and regarded by its readers; containing, as it
does, much essential information to the Miner, Millman,
Metallurgist, and other professional workers in ores and
minerals, which cannot be found elsewhere in print. It
also abounds throughout with facts and instructions ren-
dered valuable by being clearly rendered together and in
simple order. It contains 120 diagrams, illustrating ma-
chinery, etc., which alone are of the greatest value.
Price, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and
the Extraction of their Respective Metals without
Quicksilver. 1889.

This rare book on the treatment of gold and silver ore
without quicksilver, is liberally illustrated and crammed
full of facts. It gives short and concise descriptions of
various processes and apparatus employed in this country
and in Europe, and the why and wherefore. It contains 156
pages, embracing illustrations of furnaces, supplements
and working apparatus. It is a work of great merit, by
an author whose reputation is unsurpassed in his specialty.
Price, \$5, coin, postage free.

SPECULATORS' and CAPITALISTS READ THIS!

I know where there are immense deposits of coal, worth
millions of dollars. I need from twenty thousand to fifty
thousand dollars, or more, to LOCATE, EXPLOR and improve
said coal lands, much of which is upon Government land.
Any person having the money mentioned to invest can
make arrangements with the advertiser to go out with
him and see with his own eyes the immense quantity
and value of said coal lands. I am fully convinced that
any party investing in said coal lands can, in less than
two years, realize at least one hundred dollars for every
dollar invested. Any person possessing the requisite
means and meaning "business," can address for two
weeks, appointing time and place for interview,
A. B. "COAL."

ing, Electrotyping and Stereotyp-
ing done at the office of the MINING
AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

PATTEN'S CONCENTRATOR AND AMALGAMATOR COMBINED.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentra-
tor now in use. All of which any practical miner will comprehend when seeing it in operation.
The wear and tear is nominal, and the construction so simple that any miner can put it up and run it, and the
low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short
time. One machine will concentrate the tailings from a live-stamp battery.
The undersigned is now located at the Iron Works, 217 to 221 Fremont street, where he is building the
above machines and prepared to fill orders, and guarantee them to do all that is claimed. Estimates given and orders
promptly filled for all kinds of mining machinery.

Prospecting for Oil.

The circumstances which have governed oil operators in locating oil property have been many and various. Early in the history of the trade oil on the surface meant oil underneath. A location where oil was found on the surface of springs or streams, or oozing through the ground, was accepted as a favorable situation for drilling oil wells. The experience in the Pennsylvania oil regions, however, seems to prove the uncertainty of these indications. Wells were drilled in the vicinity of and in the bottom of the ancient pits on the famous Oil creek, in that State, without success. Wells have also been drilled in the immediate vicinity of oil springs, and have found no oil in any abundance. This experience would seem to prove that oil on or near the surface of the earth has but little immediate connection with the large deposits of petroleum from which the wells of the present draw their supplies. In the early years of the oil trade, in selecting a site for an oil well, a ravine or hollow was generally considered to offer advantages, possibly from some mistaken impression that the presence of the irregular and cavernous rock formation in which oil is found was indicated by the irregularity of the surfaces. There may be of course some connection, but a well so located would not be necessarily over the oil-producing rock. An erroneous impression also prevailed that locations in ravines or on river bottoms were good because the stratum of rock could be reached with less difficulty. Mr. S. H. Stowell, a very good authority on such matters, affirms that the facts are against all these theories, were there no other argument to be urged against them, and they have been proved erroneous by experience, the location of a well with regard to the surface configuration having been found to have but little to do with its productiveness.

The chief guide that for years has been, and is now, relied on in locating oil property, is the success or failure of former operations in the locality under consideration. Pioneers in new localities take most of the risks therefore. It having been once decided that the reservoir of oil is beneath one well, it is reasonable to conclude that another well, drilled in close proximity, stands a fair chance of tapping the same reservoir. Of course to this rule must be attributed, more than to any other, the development and increase of our oil fields. Still there are many instances where a well sunk in very close proximity to a producing well has failed of success. In one instance cited, a well which was quite dry at first became a producer upon having the diameter of its bore increased about an inch, proving that ever so slight a distance from the oil vein will be fatal to the productiveness of the well.

DR. ZEILE, owner of the Zeile quartz mill and mine in Amador county, died last week in Italy.

The Ohmen-Simmons Engine.

The engraving on this page represents the Ohmen-Simmons automatic balance valve cut-off engine. The engine is built in this city by W. H. Ohmen and has been patented by that gentleman and J. Simmons. The Ohmen engine has been well known on the market for some years, but this new type is a decided improvement, and the manufacturers now think they have the plainest and most perfect automatic cut-off engine in use. There are but two straight eccentric rods acting direct one on each valve, and one inside of the other. There is but one stuffing box to contend with on the whole engine, and that is the one for the piston rod. The engine however possesses all the good qualities of other first class cut-off engines. Being of a new form, new standard patterns had to be made, and these are now nearly all done.

THE OHMEN-SIMMONS AUTOMATIC BALANCE VALVE CUT-OFF ENGINE.

When accomplished two classes—"A" and "B"—will be made. Class "A" will be an engine of short stroke such as is shown in the engraving herewith. Class "B" will be a long stroke engine designed for high piston speed and not too many revolutions. Mr. Ohmen has up to this time completed three of this type of engines. One of them was for the Golden Age mills and is a 20 x 42, saving 33 per cent fuel over the old engine. One 16 x 18 has been built for the Sheridan mills; and one 8 x 9 for the United States Laundry. He has in course of construction one for F. P. McLennan's wool scouring factory, and one for Fry & Wiseman's flour mill. Mr. Ohmen says he is now prepared to build this engine from a 6 inch cylinder to one of a 30 inch bore.

THE Silverado Company, Sweetwater, which owns two locations on what is known as the Silverado lode, has four shafts sunk. In the main shaft on the Silverado claim a very rich strike was recently made. The ledge is about six feet wide and eighteen inches thick; yields ore which assays from \$1,200 to \$1,500. The remainder is good milling ore, which will work to about \$50 per ton.

COMMISSIONERS who have examined the twenty-five-mile branch of the Cascade division of the Northern Pacific railroad built east from Tacoma towards Natches Pass, found the road first-class, and will so report.

Methods of Working Breasts.

The places from which the coal is mined are known throughout the anthracite coal fields by the term breasts. But in some localities they are also often called rooms or chambers. The latter terms being applied to flat workings. In opening, ventilating and working breasts, they may be divided into three classes according to the dip of coal: 1. Wagon breasts; in coal dipping less than seven degrees. 2. Buggy breasts; in coal dipping from 6 or 7 to 10 or 12 degrees. 3. Shute breasts,—pitching breasts; in coal dipping from 12 or 15 to 90 degrees or vertically.

Wagon breasts or those into which the mine car is taken or a track laid from the gangway to the working face, admit of few variations in the method of working, and this is also true of buggy breasts; but there are several methods of

Samples for Analysis.

In selecting samples of ore, coal or other mineral substances for analysis, the object to be attained is to receive a sample fairly representing the average quality, not of hand specimens, but of the article to be shipped to the market. Take, for instance, the example of coal. When mining and shipping are already in progress the most approved plan is to take a considerable quantity (two or three shovels full) from a number of cars, or to gather it in buckets from the loading shute.

A large quantity having been thus collected, it is carefully broken down into smaller pieces, mixed thoroughly with a shovel, and thrown up in a conical heap. The heap is then quartered, and two quarters opposite each other thrown aside. The remainder is broken still finer, mixed, heaped up and quartered as before, and this process is repeated until only a few shovels full are left. This is packed and shipped to the chemist, the box or keg being covered with strong paper to prevent entrance of dirt and loss of some material. This matter is, of course, only intrusted to a disinterested material. If no coal has been mined, and the sample is to be taken from a drift tunnel or stope in the bed, a small piece should be broken from every inch of the seam, care being taken that the fragments shall be of equal amount from each part of the bed, so that they will make such a sample as would be obtained by cutting out a

block of coal three or four inches square and as high as the bed is thick. The parting bands of slate, sulphur (pyrites), etc., should always be included in the sample, unless the bed contains a thick layer of slate or bone that readily breaks loose from the coal and can be cleared from the coal in mining. In this case the parting may be represented in the sample by such a piece as would be taken if the parting were only a thin layer. As very few persons can be trusted with the selection of samples taken directly from a bed not mined, when work of this character is needed, and the analyses are to be used for any important purpose, a mining engineer accustomed to work of this kind should always be employed to gather the samples.

The first of the four large locomotives built for the Park and Ocean Railroad has been taken to the depot at the end of Haight street. From Twenty-fifth and Valencia streets the locomotive was drawn upon a truck to Haight and Market streets, and here a number of horses, four abreast, were hitched to the truck and the procession moved slowly out Haight street. There were forty-two horses in all drawing the locomotive, which weighs thirty-eight tons. The water for two or three trips is carried around the boiler. This has a double advantage—the water enters the boiler warm and requires less coal to heat it, and the weight of the water presses the driving-wheels to the rails and gives the engine greater power.

THE S. P. C. R. R. Company have received at Alameda Point three of their new locomotives and another is daily expected. A shipload of steel rails is being unloaded there, and will be laid on the new mole. An addition of about sixty miles of new steel rails will be laid from Alameda Point to Glenwood.

THE arbitrator to whom the question of wages in the manufactured iron trade in Northern England was referred, has decided upon a reduction amounting to 2½ per cent. The employers demanded a reduction of ten per cent.

CORRESPONDENCE.

New Mexican Mills and Mines.

EDITORS PRESS:—A certain Territorial paper has lately published a list of reduction mills and plants in New Mexico, which is absurdly incorrect in many of its statements. In this immediate neighborhood it states that there are two 10-stamp mills at White Oaks and one 10 stamp mill at Nogal. In fact there are at this place one 10-stamp mill erected in June, 1881, which has been run spasmodically upon custom work; a new process, 60-ton mill of nondescript character, erected in 1882 for the Homestake mine, this never ran, and never will; and the "Delaware" gold mill, erected in 1883, equipped with one 20x9 crusher, Blake pattern, two Tasker pulverizers and two Embury concentrators. This mill ran on "Solitaire" and "Little Mac" ores for say three months, or until the "pulverizers" were worn out. It did fair work to an extent far below the estimated capacity. The pulverizers are not adapted to our hard and tough quartz. The two last are idle, and will remain so until rebuilt. The 10-stamp mill is working "Solitaire" ores, and will probably run continuously for the season of '84.

There is in Nogal canyon a fine 15-stamp mill, erected in 1883 to work ores of the "Rockford" lode. This is idle, pending litigation in regard to the mine.

In Dry gulch, one mile east of this last mill, is a fine 5-ton roller mill, with nickel patent pan, built by Gill & Lesnet for their "American Boy" lode. This has run continuously since its erection. There has been but one clean-up. Results: 743.75 ounces gold, \$55 fine.

Superintendent Sligh has just erected a 12-foot arastra at Vera Cruz, in Nogal district, to make a 100-ton test of ore from the Vera Cruz lode.

The New Mexican list makes no mention of the 5-stamp concentrating mill on the Cooney mine in the Mogollon mountains. The more strange, as it is so far the only successful concentrating mill in the Territory.

I will leave to others the task of pointing out errors in respect to other parts of the Territory. Last week I visited the "American Boy" lode in Dry Gulch, the property of Messrs. Gill & Lesnet. This lode was located by Mr. Gill in 1869. He held it for several years at the peril of his scalp. When the Mescalero Apache reservation was created it included the location of the mine, and Mr. Gill was driven off without the slightest warrant of law. Upon the reduction of the reservation in 1882, he resumed active development. This winter he and his partner erected a small roller mill; capacity, four tons in twenty four hours. The mine is under the direction of the owners, and they run their mill themselves. As stated elsewhere, they cleaned up after a run of 40 tons, and realized over \$13,000. About one-half of this was selected ore. They have exposed a vein 90 feet wide in granite walls, 60 feet is quartz, every inch of which prospects. Bands of from half an inch to a foot in width are strung with wire and shot gold, and pay from 10 cents to \$4 per pound. No great depth has been attained as yet, as until starting up their mill, the owners could not afford deep workings. As it is, and if there were no more of it than can be seen, the mine would be a wonder. I write of this property the more freely because it is not for sale.

It does not, however, stand alone in this district. There are others as good, or nearly so. This property will be equipped during the season of 1884 with a much larger mill. But even with the small one, it will be a noticeable producer. For the season of 1884 the gold production of Lincoln county will for the first time become of importance.

It could have reached a heavy production in 1882 had the mining machinery brought in been brought and controlled by men having knowledge and experience. The mill in Nogal canyon and the small mill in Dry gulch were the first erected in the county by a man of experience. The owner of the first mill built at this place has learned the art and mystery of milling gold ores, and now does good work, but he learned at a heavy expense to himself and the camp.

White Oaks, N. M., April 18, 1884.

How to Survey a Bore-Hole.

In a paper read before the Victorian Institute of Surveyors last September by Mr. E. F. Macgeorge, there is an account of a system, devised by the author, for surveying and mapping the true direction of bore-holes.

Serious deviations from the vertical of bore-holes made by rock drills, have often caused much protracted and expensive search for mineral deposits proved by them, and have led to many suggestions for the discovery of such "lost bore-holes;" but to Mr. Macgeorge is due the credit of making this possible, by simple, and what seems an efficient method.

The surveying instrument, or "clinostat," is a cylinder of glass, six inches long, fitting into a brass jacket within a guiding tube geoscope. The lower end of the cylinder terminates in a short neck and glass bulb about one inch diameter, within which is a magnetic needle, semi-floating under a buoy, so as to stand upright upon its pivot. This bulb is filled with a hot

solution of gelatine which sets and holds the needle at its bearing.

Passing through an air tight stopping at the other end of the glass cylinder is a small glass tube, terminating in another bulb above, and containing a glass plummet with float, which, like the magnetic needle is immersed in the gelatine solidifying fluid.

"The fluid then contains within itself an automatic registration of the inclination and azimuth at which its containing vessel cooled, while, let us say, 500 feet deep in the bore-hole to be tested; and it is easy therefore after its withdrawal, to tilt it to the same angle and to the same quarter of the compass as before, by simply bringing the embedded plummet and needle to the vertical and northerly directions respectively."

The clinostats in the guide rod are six in number; and, as tests are taken at several points in the bore hole, great accuracy can be obtained.

Each clinostat, with its congealed contents, is now placed in succession in a recording instrument or clinometer, where by means of two cross visioned telescopes kept truly in the same plane at every angle of inclination by a parallel motion, the clinostat is brought to the same angle of inclination at which it set; and by a circular mirror below the needle bulb and into which is reflected the image of the needle, there is the means of plotting the angle of direction.

It is a well-known fact that bores frequently deviate from the plumb, and considerable error, even amounting to as much as 40 feet in a bore of 180 feet deep, has been observed. Mr. Macgeorge's ingenious device for surveying bores, which he states has in many instances saved large sums in hap-hazard mine driving through the hard rocks of the auriferous reef district of the Antipodes, might frequently be of value in our own mining operations.

Appeal to California Representatives.

To our Honorable Senators and Representatives from California in the Congress of the United States:

The Manufacturers' Association of California respectfully address you this memorial in relation to the present situation regarding patents for inventions, and earnestly invoke your active opposition to such bills as have been or hereafter may be introduced into either branch of the National Congress hostile to the progress of science and the useful arts, by limiting the just protection to their respective discoveries and appliances.

It is with surprise and fear that we have recently learned of bills greatly impairing, if not practically destroying, the rights heretofore conferred upon inventors, having been favorably considered by the House of Representatives, and we view with anxiety the action of the Honorable Senate upon them, and with alarm the consequences which may follow their enactment.

We consider the proposed changes radical and unjust, and liable to seriously injure many and great existing interests, and prevent completion of numerous prospective enterprises by withdrawal of capital and confidence, and raising perilous obstacles to our country's inventive, industrial and manufacturing progress.

We therefore earnestly and most respectfully protest against the proposed changes, and all similar provisions which abridge the usefulness of the Patent Office Department or impair the protection heretofore afforded.

In presenting this request and protest, we beg to remind you of some great facts of history which are a part of the common knowledge of the world, viz.:

That the general advance of each civilized nation in knowledge and intelligence, in enjoyment of increased comforts and luxuries and accumulation of wealth has been greatest where inventors are best protected, and that this advance is chiefly due to their discoveries and productions.

That the patent laws do not, nor have they ever given, the inventor anything beyond an exclusive right for limited time to use or sell that which he had himself created. For this reason the country has lost nothing nor can it lose anything by continuing the patent laws as wisely provided for in the Constitution of the United States, in all their force and integrity.

That the great inventions and useful discoveries made by inventors in the United States have constituted an advance highway on which our country marches, a proud leader of the nations of the world in all that makes a people intelligent, comfortable, rich, happy and independent.

That under the incentive and protection afforded to inventors by our patent laws, inventions and improvements have multiplied rapidly, furnishing easier and cheaper methods for agriculture, manufacturing, mining, transportation and travel.

That the hours of daily labor have been reduced, while the means of livelihood, with enlarged comfort in our homes, have been greatly increased through the changes these inventions have wrought.

The benefits derived by the country from inventive genius and mechanic skill, are so immeasurably greater than inventors have gained from the people, that comparison ceases.

Referring to these general truths, we send you this Memorial protesting against the threatening action inimical to the patent laws, and earnestly soliciting your hearty efforts towards continuing the wise policy which has

added so much toward the expansion, prosperity, strength and glory of our nation, and respectfully express our desire that you will exercise your influence to preserve the body and intent of our patent system, and that all changes will be confined to details for correction of abuses to make it more effective.

Manufacturer's Address to the People of California.

The "Manufacturers' Association of California" is an incorporation without capital stock, recently formed to promote manufacturing interests of this coast, by establishing more intimate and reciprocal relations between the various mechanical and other industries.

Its membership already embraces upwards of one hundred names, representing nearly every prominent manufacturing and laboring pursuit, engaging large capital and many thousand employees.

It is desired to extend this membership, to include every industrial and manufacturing interest, however small or remote, in the State; believing such combination will create new, and advance existing enterprises.

The special object being to stimulate and assist local production and manufacturing, by mutual encouragement, patronage and protection, thereby increasing the sources and means of employment for many thousands more of our people who wish and only wait opportunities to make their time and labor useful.

The growth within few years past of manufacturing business in this State has been exceptional, indicating that we have all the elements of self-support and preparing the way for new enterprises as population increases, and cultivation of the soil extends.

The progress hitherto made warrants the statement that products and manufactured articles of our State are equal and often superior to those from abroad.

A larger proportion of the articles consumed or appliances used here can be supplied from our own resources, if home labor is fostered by giving its products preference; thus capital will be encouraged toward factories, workshops, and raising raw material to be converted into food, clothing, fabrics, and implements constantly required.

The rapid extension of railroad connections with adjacent States and territories, their flowing population, and resources to be developed, together with increasing ship commerce, and demands for export, furnish new markets for products of our soil and manufactures, affording most encouraging promise.

The prospects of this year in grain, fruit, wine, wool, dairy and cattle districts are unusually favorable; whilst the constantly increasing value of our iron, leather, lumber and other industries adds new impetus to all contingent traffic.

Money paid for productive labor becomes now capital. In proportion as it is distributed among our people, conditions of self-reliance and self-support will improve, wealth accumulate, and all interests, whether of land, improvements, or the varied employments of floating capital, become secure and profitable.

In view of these facts we earnestly invite your co-operation, confident that harmonious action will promote common benefit by enlarging the field and variety of industrial occupations to the advantage and prosperity of all.

The influence of such an association, composed of many and great interests and varied industrial pursuits located throughout the State, by their numerous employees and dependants united upon a good purpose, will be an important factor in social and public welfare.

Let all assist by personal effort to develop and support local enterprises, that needed capital, now too often withheld, be attracted to them and secured in its investment; respectable remunerative trades and occupations afforded to those who seek employment, particularly the young of both sexes, so that industry and economy may flourish, and prosperity reach every part of our broad commonwealth.

The office of the Association is Room 43, Merchants Exchange No. 431 California Street, San Francisco, where the secretary will receive visitors and give necessary attention and information upon all matters relating to its business and purposes.

A. S. HALLIDIE, President.

IRVING M. SCOTT, Vice-President.

N. W. SPAULDING, Treasurer.

Geo. C. HICKOX, Secretary.

Directors—W. T. Garratt, Arpad Haraszthy, Isaac Hecht, Alanson H. Phelps, A. L. Tubbs, Wm. Harney, S. P. Taylor, David Kerr.

Importations of Nickel

The importations of nickel have varied greatly from year to year for the past five years, as shown by the annexed table. The steady increase in the amount of nickel oxide and alloy of nickel with copper from 8,518 pounds in the year 1878 to 177,822 pounds in 1882 is noticeable, and is due to the fact that a large part of the nickel imported is now entered as "alloy," while containing as high as 95 per cent of nickel and only 5 per cent of copper, being nearly as pure as the nickel of commerce made a few years ago before the discovery of the Nonneau ores. A compound of 50 parts of nickel and 50 parts of copper was then commercially known as nickel alloy. At present nickel is made, or can be made, commercially pure, carrying only 1 or 2 per cent, or even less, of impurity.

The following table shows the amount of

nickel, nickel alloy, etc. (including both entries for immediate consumption and withdrawals from warehouse for consumption), imported into the United States during the fiscal years specified:

Years.	Metallic nickel.		Nickel oxide and alloy of nickel with copper.	
	Quantity.	Value.	Quantity.	Value.
	Pounds.		Pounds.	
1878.....	7,486.50	\$8,837	8,518.00	\$7,847
1879.....	10,496.50	7,823	8,317.75	5,570
1880.....	33,276.00	25,758	61,880.00	40,311
1881.....	17,083.00	14,563	135,744.00	107,627
1882.....	22,006.00	17,924	177,822.00	125,736
Total.....	97,008.00	74,851	392,270.75	\$287,091

There were no importations of nickel ore at the port of New York during the Year 1882.

The so-called "nickel alloy" is made for the American market by the Vivians, of Swansea, England.

Iron Shaft Tubbing.

The rupture of the cast-iron tubbing of a shaft at the Banoux colliery, in the province of Liege, in Belgium, claims the earnest attention of mining engineers. The accident is striking, both from its novelty and from the fact that none of the universally adopted elements of security were absent. A committee of eminent engineers had designed the work, the quality of the material and workmanship was beyond question, and the directorate had even increased the dimensions recommended by the engineers.

The tubbing of the Banoux shaft was required to resist the pressure of 42 meters (139 feet) head of water. It extended from the thill of a coal seam up to a height of 44 meters, the distance to the surface being 60.5 meters; and it was composed in height of seventy-two sections of 0.60 meter each. This length of tubbing of 44 meters was divided into three equal portions, in which the thickness of the metal differed. In the lower portion, this thickness was 34 millimeters (1.33 inches); in the middle portion, it was designed to be 26 millimeters; and in the upper portion, 19 millimeters. But, during the execution of the work, these portions were increased to 30 and 26 millimeters respectively. The shaft was not circular, but four-sided, the sides being equal and curved, a form common on the continent. In this shaft, one segment was made to span the whole distance on each side. The segments on two opposite sides were curved to a radius of 3.85 meters (12.63 feet), giving a chord of 2.5 meters, and a versed sine of only 0.22 meter. On the other two opposite sides, the segments were curved to a radius of 3.50 meters, giving a chord of 2.60 meters, and a versed sine of 0.27 meter. The segments were bolted together at the angles in the usual manner, the joints being made with strips of lead 3 millimeters (0.118 inch) thick. On the inside of each segment, were three strengthening ribs, each 85 millimeters (3.34 inches) deep. It is customary to calculate the thickness of such tubbing on the assumption that the shaft is circular, and of a diameter corresponding to the curvature of the segments. Calculated on this basis, the thickness of the lower tubbing should have been, for the larger diameter, 32.34, say 33 millimeters, and for the smaller diameter 29.4, say 30 millimeters. The thickness actually given was 34 millimeters in both cases. Thus, the dimensions adopted were not only arrived at in the manner sanctioned by experience and in conformity with the common practice, but as an additional security, these dimensions were slightly exceeded. Thus, nothing was wanting to give confidence in the solidity of the structure. Yet this tubbing, calculated, as it was supposed, with a wide margin for safety, to resist a head of water of 42 meters, gave way when the head had reached only 35 meters. The rupture occurred in the middle of the segments, and extended from the bottom to a height of 18 meters through thirty-one successive segments.

The purpose of the author of this report is to show that tubbing of this character is not subjected solely to a stress of compression, as in the case of circular shafts; and that consequently the calculations which are based on that assumption are erroneous and dangerously misleading. He demonstrates that such segments are exposed to a transverse strain by the extraneous being forced outward against the pressure which holds the center in position—that is, the force which is brought to bear upon those pieces tends to cause flexure, and the strain thus set up increases with the radius of curvature. Such a strain tends to break the segment in the middle, in the manner in which the rupture occurred at Banoux. A careful measurement of some of the deformed segments showed that the versed sine had been diminished by from 1 to 2 centimeters, while their chords had been increased by from 2 to 4 centimeters. The author recommends the adoption of a greater thickness of iron in these cases, and suggests the necessity of taking precautions to counteract the tendency of the angles to yield under the action of the external pressure. In the new tubbing designed for the Banoux shaft, these suggestions have been acted upon, and the structure is probably the most massive that has yet been constructed.

Abstract of a paper by P. Banoux in *Annales des Travaux Publics de Belgique*.

MECHANICAL PROGRESS.

Rotary Engines.

Prof. R. H. Thurston, in a recently published communication, gives the following excellent summary of the comparative merits of the reciprocating and rotative types of the steam engine, which will be found of special value to those interested in the development of the latter type of engine. It is an admirable and concise *resumé* of the present status of the subject under discussion:

"Advantages have been expected of the rotary engine by the advocates of that form of motor which are not looked for by the well-informed engineer. It is assumed that the reciprocating engine is essentially defective; that the conversion of the reciprocating motion of the piston into the rotary motion of the crank and fly wheel involves, necessarily, some appreciable loss of power and efficiency; that the variation of speed of the reciprocating parts, from a state of rest at the 'dead points' to maximum velocity at half stroke, must necessarily cause loss of power, increased wear and tear, and dangerous impact at high speed, and must thus restrict, to a very serious extent, the development of greater power by the adoption of higher velocities of piston. It is these notions which have been the usual stimulus to inventors who have, during the past century, been endeavoring to produce rotary engines capable of competing successfully with the always standard reciprocating machine. The patent records teem with such devices, many of them ingenious, more of them crude and unmechanical. Rotary engines have usually proved to be wasteful in their use of steam, subject to rapid depreciation in power and efficiency, and to great loss of power by friction of working parts. Engineers are, therefore, likely to look with interest, and with a little surprise, upon a motor of this class which is not subject to these defects, even though it may not prove to be the superior of the best engines of the more common type.

"But the assumed objections to the reciprocating form of steam engine are, to a considerable extent, imaginary. The conversion of a reciprocating motion into rotation does not necessarily involve loss of power, and need not, in a good engine does not, cause objectionable jar or injury to the working parts. The limit to the increase of speed of the modern 'high-speed' engine is not beset by the difficulties of the kind above described met with in its operation, but rather by the impossibility of carrying more than a certain amount of power through fast-running machinery with absolute certainty that lubrication may be secured, without interruption for an instant, day after day, indefinitely. The inertia of parts, which has been so generally assumed to be detrimental to the action of the machine, has an equilibrating effect with the irregularity of steam distribution due to the expansion of the steam; and this balance may be adjusted for speeds greatly exceeding even the highest attained by the most radical of the high-speed engine builders of the day. The rotary engine has not, therefore, the advantage in this respect claimed for it in the past by many engineers, as well as by non-professionals. It has, however, evident advantages which have been hitherto more than compensated for by the apparent impossibility of securing that economical distribution of steam which is easily and satisfactorily obtained in the standard forms of engine, and by the failure of nearly every form of rotary, in competition with the reciprocating engine, when compared with respect to freedom from internal friction and leakage of steam past the piston. It is always safe for the layman, when asked to put his capital into rotary engines, to assume that the machine possesses these defects to a fatal extent, unless the contrary has been proved to be the case by careful tests made by engineers of known skill and integrity.

"The engineer is, therefore, pleasantly surprised when he finds one of this class of engines doing good work, and he will be still more pleasantly surprised when he finds the difficulties overcome which have hitherto been met in the endeavor to secure good steam distribution, high economy and perfect regulation, such as is seen in the best reciprocating engines, combined with the undeniable special advantages of the rotary engine. These impediments being removed, the rotary will supersede the reciprocating engine—but, I think, not till then, except for very small powers. Our small reciprocating engines do not compare favorably with larger sizes, in respect either to economy, exactness of regulation, or power per pound of weight of machine. They are usually capable of great improvement; but a small machine of this class will probably never do as good work as a large one. For the present, at least, the best rotary engines must compete solely with the smaller reciprocating engines."

Improvements in Men and Machines.

It would be a curious study to ascertain how far the improvement in machines and in tools had kept pace with that in the skilled mechanic. One thing is certain, at the beginning of the inquiry, that a skilled mechanic is of just as much value to-day as ever. How much he has improved is a question for scientific examination rather than one for absolute statement. It would be a queer assertion that the men of fifty years ago were inferior to those of the

present. All the facts of the past, as well as those of the present, show that our present mechanics are no more mechanics than those of half a century ago. All the great improvements in hand tools and machine tools for the last fifty years have come from the individual efforts of men who have done their work before the present advent of machine and automatic tools. These men—these workmen and inventors—made possibilities out of suggestions, and realities out of imaginings. To them belong the realities of the present machine shop.

It would seem from this that it is not the tools and the appliances that make the workmen, but the workmen who make the tools. There are just as good mechanics to-day, with all our mechanical appliances for good work, as there were when every job required a new arrangement of tools for work. In fact, the improvement in machines presupposes the capacity of the machine makers.

And yet these improvements have their influence on the workman; the better the tool, the more effective the workman. There are gray headed, almost superannuated, workmen in our shops who have voluntarily discarded all their old time notions to take up with some "new fangled trick" that has been proved to be an advance toward perfection. Every improvement in tools—induced and perfected by mechanics—tends to an advance in the true mechanical improvement of the workman.—*Scientific American*.

Old Castings.

The art of casting in metals is so dependent on the clay model from which the mold is obtained that it might almost be assumed *a priori* that improvement in plastic art would necessarily lead to a great development of metallurgical skill, and accordingly we find two celebrated Samian artists, Theodorus and Rheucus, credited with the invention of casting in bronze at a date probably not many years distant from that of Butades. When ancient writers speak of casting in metal as the invention of the two Samian artists, we must understand by this statement that improved kind of casting in which the metal is poured between the mold and a central bore, and which is called hollow casting, in contra-distinction to the more primitive process in which the molten metal entirely fills the mold, and which is therefore called solid casting. We know that this clumsy solid casting was familiar to the Egyptians, the Phœnicians, and the Assyrians centuries before the time of Theodorus, and we find it used for the handles of large bronze craters in Mycenaean tombs, and in small figures such as are found in the lowest stratum of the soil at Olympia. It was, however, unsuitable for statues on a large scale on account of its great weight and cost; therefore, it was that most Greek statues in bronze were originally made in separate pieces of metal hammered out on a mold, and then nailed together on a wooden core. Such figures, called *Sphyrelata*, or hammered work, were still extant in Greek temples in the time of Pausanias.

The invention attributed to Theodorus and his brother substituted for this primitive kind of metallurgy an easier and surer process, which after having been brought to an extreme perfection by the Greeks, has been handed down to modern times with little, if any, improvement in its technical processes.

STEAM ENGINE PRACTICE.—The introduction of "high-speed" engines in machine shops and iron and other metal manufacturing establishments is not satisfactory. There are places where the rapidly running engines, with a piston speed of 600 or more feet per minute, are at home, but their proper place is not the machine shop, if reports and facts agree. One of the largest and best known manufactories of metal goods in New England ran its works satisfactorily with a slow moving engine. To accommodate additional demands, the cylinder was re-bored and other changes made that added largely to the capacity of the engine. Except for this enlargement the engine required no doctoring, and before and after the change could be relied upon to do its work. An addition to the works was made three years ago, and a little buzzing engine put in to run it. The claim was made that the little wasp had more power than the old-fashioned traveler. But the result comes in frequent repairs and inconvenient stoppages, \$600 having been expended in repairs on the rapid moving engine within two years—four times as much as has been expended on the old engine, that has run evenly for 18 years. There are slow moving engines of 30 years ago or more in the New England States, huilt, some of them, by concerns now out of existence, and bearing the names of men on their claim plates who have "gone over" and left only their memories as mechanics, which do their work as honestly as some of the machines that to-day assume to displace them. They were built for their work, and not to illustrate a theory.—*Scientific American*.

MASSIVE STEEL FORGINGS.—Sir Joseph Whitworth & Co., of Manchester, have just completed several large steel forgings, made from their patent fluid-pressed steel. One of these is a solid forging, which is to form the tube or barrel for a 63-ton gun; the length of this forging is 34 feet 7 inches, and the greatest diameter 29 inches. In the rough it weighed about 31 tons, and finished for boring, 28 tons,

SCIENTIFIC PROGRESS.

An Oil Spot in the Gulf of Mexico.

Lieutenant Stamm, of the revenue cutter Andrew Johnson, recently gave the following description of a remarkable "oil spot" in the Gulf of Mexico, about which there has been much discussion among scientists recently. The facts in connection with this locality are wonderfully corroborative of the claim set up for stilling the sea waves, by the artificial application of oil to the surface of the sea. Lieutenant Stamm describes the "spot" as follows:

"The oil spot is situated about ten miles south of Sabine Pass, into which flows the Sabine river to the Gulf of Mexico, and it extends two miles along shore, and seaward about three-quarters of a mile. There is nothing remarkable about its appearance during calm weather, but in a gale, when riled, it assumes a reddish hue and is thick and muddy. The greatest depth, where comparative quietude reigns while the elements are at war is 12 feet, so none but vessels of moderate draft can enter. I have, with very little effort, from one of the ship's boats pushed a pole thirty feet in length down into the soft stratum. A storm from the northeast, by way of east to southeast, has a rake of from 300 to 700 miles across the Gulf of Mexico into this mystic haven. During a gale the spot is wonderfully defined. Looking seaward the scene is grand. An acre of towering foam marks the abrupt dissolution of the lashing seas as they thunder toward the shore. This occurs in about three fathoms, or eighteen feet of water, from which the storm-driven craft, creaking and straining in every timber, emerges and suddenly finds herself reposing like a child rocked in its mother's arms, hemmed in by a wall of wrath, where the weary mariner can be lulled to rest by the roar of the winds. I have frequently seen the decks of the vessel scrubbed with the mud from this spot. It is soapy, and its cleansing properties remarkable. There are no streams in the locality emptying into the Gulf, and the mud of the Sabine river to the northward contains none of the properties here found. If there is oil, it comes from the bottom surface. The place is termed the 'oil spot,' not from any known analysis of its nature, but simply from its condition; it has no troubled water. During three-fourths of the year the neighborhood of the oil spot is the Olympus of the mosquito."

The Science of Thinking.

The object of the teacher is to teach to think. The pupil thinks enough, but he thinks loosely, incoherently, indefinitely and vaguely. He expends power enough on his mental work, but it is poorly applied. The teacher points out to him these indefinite or incoherent results, and demands logical statements of him. Here is the positive advantage the teacher is to the pupil.

Let us suppose two pupils are studying the same lesson in geography or grammar or history. One reads to get the facts; he fastens his eye on the page and his mind to the subject before him; he makes the book a study, and acquires information from it; his object is to acquire knowledge. He attains this end. The other also studies the book, but while reading he is obtaining lessons in thinking. He does not merely commit to memory; he stops to see if the argument is sound; he analyzes it to see if the conclusion is warranted by the premises.

The one who thinks as he reads is quite different, it will be seen, from him who simply learns as he reads. To read and think, or to think as one reads, is the end to seek. To teach to think is then the art of the teacher. The reader for facts gets facts; he comes to the recitation seat and recells those facts. His mind, like Edison's phonograph, gives back just what it received. While this power is valuable, it is not the power the world wants.

The teacher will find his pupils come to the recitation to transmit the facts they have gained. He must put them in quite another frame of mind. Instead of recitations, they must be made into thinkers. The value of the teacher is measured by his power to teach the art of thinking.—*Teacher's Institute*.

LATE OBSERVATION ON THE PLANET JUPITER.—Among the papers read before the recent meeting of the American Association for the Advancement of Science, was one upon the planet Jupiter, by G. W. Hough, of Chicago, in which he remarked that the rapid motion of revolution of the planets, by changing the positions of the markings on the surface to our line of sight, makes great apparent differences in their shapes and sizes. This has perhaps been the occasion of reports of sudden and great changes upon the surface. The changes are not sudden, but are gradual, and many of the features are permanent. Minor changes are constantly in progress in the equatorial belts. The author recently observed the belt drifting down toward the red spot, but, although it partly surrounded it, they did not coalesce, and the spot forced a scollop into the belt—a very curious phenomenon. The author saw a satellite pass over this red spot, though the satellites are not visible when on the white part of the disk. He had also had a chance to compare shadows of satellites on the disk and on the spot, and both are dark. The red spot had

seemingly retrograded during the past four years; that is to say the rotation of Jupiter has seemingly increased from 9 h. 55 m. 33 s. to 9 h. 55 m. 38 s. The future observer should attend more carefully to what he sees, and theorize afterward.

THE MATRIX OF THE DIAMOND.—Until the South African mines were discovered the diamond was always found in sands and gravels, different from the mineral in which it was believed to be formed. At Griqualand West, however, the consolidated eruptive mud of the mines was believed by some to be the true matrix of the diamond; but opinions differed on the question, and arguments were found on both sides. M. Chaper, a French geologist, has, however, during a scientific mission to Hindostan, succeeded in finding the diamond in it, mother rock. At Naizam, near Bellary, in the Madras Presidency, M. Chaper has found the diamond in a matrix of rose pegmatite, where it is associated with corundum. The tract of country is almost denuded of trees, bare and rocky, and the rains wasting the rocks, every year expose fresh diamonds in the soil. The rock is traversed by veins of feldspar and epidiotiferous quartz. Here the diamond is always found, associated with epidiotiferous rose pegmatite. The diamond crystals observed are octahedral, but less distinct in line than the stones of South Africa, which seem to have been formed in a freer matrix. It follows from M. Chaper's discovery that diamonds may exist in all rocks arising from the destruction or erosion of pegmatite, for example, in quartzites with or without mica, clays, pudding stones, etc.

ASSERTED CHANGES ON THE MOON.—An eastern astronomer claims to have discovered within a few weeks past that something unusual is going on in the great peak of Tycho Brahe, a high mountain which has always been a prominent object on the eastern side of the moon. Tycho is a volcanic crater nearly 20,000 feet high and fifty miles in diameter, and it had up to within a few days a peak a mile high standing in this crater. This peak, which was only a bright spot in the midst of a black crater, it is asserted has suddenly grown to be a gigantic mountain nearly filling the entire basin of the crater and towering above every other mountain in the moon. It is estimated now to be thrice as high as it was, and promises some startling phenomena. The signs of a renewal of volcanic action in the moon began to be discovered nearly a century ago; but as yet no announcement of that kind has been verified by careful after examination, and the general opening among Scientists is that the moon is really a dead globe, and that no further changes will ever be observed on its surface.

SELENETROPISM.—Ducharte was led, by the influence which a light of very feeble intensity exercises upon heliopic movements, to vary the experiments by using moonlight. He sowed seeds of plants which were very sensitive to light, such as *Lens esculenta*, *Erym lens*, *Vicia sativa*. When the plants were a few centimeters in length, he put them in a dark place, where he kept them until the night of the experiment. The stalks became slender, long and white; the leaves developed slightly, with a light yellowish tinge. On three successive nights when the sky was exceptionally clear, the plants were placed behind a large window with a southern exposure, so that they received the direct light of the moon from 9 p. m. to 3 a. m. From the very beginning of the exposure the stalks began to head, so as constantly to present their concavity and the terminal leaf bud to the moon, following it in its course.—*Comptes Rendus*.

A LONG-DISTANCE TELEPHONE.—Mr. Webster Gillett, of Ypsilanti, Mich., claims to have solved the problem of adding battery to line almost without limit, and to have overcome the difficulty hitherto experienced in using a telephone over great distances. This he does by utilizing a number of independent local batteries, induction coils and deviating points simultaneously. If the number of cells of the battery could be increased without limit, and still not burn the low conducting medium, Mr. Gillett says, it would be possible to speak at almost any distance with an ordinary telephone. His system, he claims, overcomes this obstacle to the use of many cells.

ANALYSIS OF CHROME IRON ORES.—The insolubility and infusibility of chromic iron render its analysis one of the most tedious. Schwarz recommends smelting the finely pulverized mineral with chlorate of potash and caustic potash in a silver crucible. The fused mass is dissolved in water, and the quantity of potassic chromate estimated by running in a solution of ferrous sulphate, then titrating the excess of the latter with permanganate solution. The residue insoluble in water is dissolved in hydrochloric acid, and the iron titrated with stannous chloride. A good silver crucible will stand 100 fusions.

MICROBES are those microscopic plants which abound everywhere and cause disease and decay. They include the germs of disease in whatever form they exist, and the spores of the plant as well as its perfect form. The germs which cause cholera, measles, diphtheria, etc., are microbes, and so are those which cause an apple to rot, a can of peaches to mold, a barrel of cider to turn sour. It includes every form of bacteria and micrococci.

TABLE OF CONTENTS.

EDITORIALS.—Prospecting for Oil; The Ohmen-Simmons Engine; Methods of Working Breasts; Samples for Analysis, 301. Passing Events; Mining and Scientific Press; Poultry Notes; A New Treasure Vault; The Patton Concentrator; Cost of Mining Copper, 304. Hold on a Bit, On Rock Drills—No. 2, 305.

ILLUSTRATIONS.—The Ohmen-Simmons Automatic Balance-Valve Cut-Off Engine, 301. Sectional View of the Brandt Hydraulic Rock Drill, 305.

CORRESPONDENCE.—New Mexican Mills and Mines, 302.

MECHANICAL PROGRESS.—Rotary Engines; Improvements in Men and Machines; Old Castings; Steam Engine Practice; Massive Steel Forgings, 303.

SCIENTIFIC PROGRESS.—An Oil Spot in the Gulf of Mexico; The Science of Thinking; Late Observations on the Planet Jupiter; The Matrix of the Diamond; Asserted Changes on the Moon; Selenitropism; A Long Distance Telephone; Analysis of Chrome Iron Ores, 303.

ENGINEERING NOTES.—A Railway Through the Sahara; The Grandest Stairway in the World; How Long Would it Take to Fill the Sahara; A Twelve-Million Bridge; The Messina Tunnel; A Prize for Electricians, 307.

USEFUL INFORMATION.—To Get Rid of Clinkers; An Elastic Lacquer; Burning Water Gas; Woven Belts; To Prevent Scratching Matches on Paint; To Make Yellow Oiled Clothing; To Cure Bacon Without Smoking; Paper Soap; Profitable Inventions, 307.

GOOD HEALTH.—Magnetism as a Healing Agent; Pure Extract for Bathing; A New Cure for Cancer; Artificial Human Milk; Rush of Blood to the Head; Cor-poral Punishment; Inoculation for Rabies, 307.

MISCELLANEOUS.—How to Survey a Bore-Hole; Appeal to California Inventors; Manufacturer's Address to the People of California; Importations of Nickel; Iron Shaft Tubbing, 302. Recent Contributions to the California State Mining Bureau, 306.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 303.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 312.

Passing Events.

From all parts of the higher mountainous regions come accounts of the opening of spring, and in many localities which have been locked up for months the miners are now going to work. The prospectors who have been waiting so long for a chance to begin their labors are now roaming the hills and now we shall hear of the usual "spring strikes."

The Comr d'Alene rush still continues. Thousands of men are going up to these new Idaho mines. The accounts from there vary greatly. In our mining summary will be found the latest news from the region.

May has opened warm and pleasant and there is promise of a prosperous year in California.

The American Minister in Mexico has forwarded to the Department of State a copy of a decree issued by the President of the Republic, ordering that on and after May 15th the duty on all goods imported to that country be increased 5 per cent.

BUTTE receives and ships more freight than any ten towns on the line of the Northern Pacific Railroad between Portland and St. Paul.

The Anaconda Company last month paid out \$40,000 for wages and supplies at the smelter, in Deer Lodge county, Montana.

Mining and Scientific Press.

There is no paper in the country which gives such complete attention to mining of the precious metals and mechanical matters in all their details as the MINING AND SCIENTIFIC PRESS. It has been published almost since its inception by its present proprietors, who know the wants of the constituency that they serve, a fact abundantly proven by their business success. A few weeks since they concluded that the time had arrived when they could consistently lower the price of annual subscription to \$3 from the long-standing one of \$4. In doing this they look to their reward in an increased subscription list. This is proving correct, for the circle of readers of the PRESS is decidedly increasing.

Those of our old readers to whom the thought occurs will do us a favor by mentioning this reduction in price to others who they think would be interested in such a publication. To many persons the difference of a dollar in the yearly subscriptions would deter them from becoming regular readers. Now they can be assured that they will not be able to find a better cheaper or finer paper anywhere. All the departments are carefully edited and in them will be found all the current news and information of use to our readers.

We have a large list of subscribers among the hardy prospectors and miners of this coast, to many of whom the PRESS has been a weekly visitor for years. They appreciate and like the paper, feeling that they will always find in every issue something of value to them in their every-day work. We have endeavored to gather all that is practical for the use of our readers, and have avoided taking up space with mere scientific theories or idle speculations. What we give our readers we intend to be useful to them. We hope to keep all our old subscribers and add many more this year, and will improve the PRESS as opportunity admits. To do this to the extent desired by the publishers we need the co-operative assistance of all who are now on our list, and thousands more who would find it profitable to read the PRESS, and who may soon become its patrons if, their attention is properly called to it by its old friends and readers who have already enjoyed its advantages.

Foundry Notes.

At the Dow Steam Pump Works, in this city, they have just completed and shipped a patent differential compound plunger pumping engine of an entirely new pattern. It was made for the Spring Hill Water Company of Seattle, W. T. The pump weighs 25 tons, and is 25 feet long. The bed is very heavy, and is made in two sections. The diameter of the high pressure cylinder is 18 inches, the low pressure cylinder 36 inches, and diameter of plunger 16 inches; the length of the stroke is 36 inches. The capacity of the pump is 1,500,000 gallons in 24 hours; static head 350 feet.

This pump was made from designs by Mr. Dow. The details of valve motion are the subject of a patent now pending. The peculiarities are in the controlling action on the engine; that is, in its regulating the speed of the engine as well as in holding it against any appreciable increases of speed if anything gives way.

This is really a new departure in this line here—building anything of this class which is both of home design and home production. There have been mining pumps, but for a compound direct-acting pump, with self-acting valve motion of novel construction, this is the first effort of any magnitude. The general design is quite new, and the form strong and compact.

Mr. Dow is about introducing another novelty in the shape of an independent air pump and condenser, one of which, by the way, goes with the pump we have been describing. The use of this makes the large pump a compound condensing one. Being independent, it is applicable to any engine which they may want to turn from a high pressure or compound into a compound condensing one. Mr. Dow is going to introduce this as fast as he can here. The air pump is driven directly by a steam cylinder, independent from the main engine. The condenser is attached to and directly above the pump. The exhaust from the engine is led to this condenser above the pump.

The peculiar advantages of this are in being able to run the air pump independent of the main engine as well as creating a vacuum before starting the main engine. It is independent in its action all through. There is a good field for an appliance of this kind.

A New Treasure Vault.

At the U. S. Sub-Treasury in this city some work has just been completed of a character which reflects credit on our California mechanics. This is the new vault and door which has been made by the Phoenix Iron Works (E. A. Rix), of this city. The vault is 20 feet long, 10 feet deep and 8 feet high. The iron plates are three-eighths of an inch thick, all planed, fitted and screwed strongly together. The foundation of the vault is made of Ransome patent concrete, and through this is a network of electrical wires, so arranged that should one of them be cut an alarm will ring. As the concrete is as hard as the hardest stone, it would be impossible to cut through without breaking the stone and cutting or breaking some of the wires. The main feature of the whole, however, is the door, which is as fine a piece of mechanical work as has been done in this city. The neck and door weigh 5,500 pounds, the door itself weighing a ton. It is two and a quarter inches thick, and is composed of four plates of iron, two plates of steel, and two of welded iron and steel. This latter is called "iron-center steel." A sheet of iron is placed between two plates of steel, and is then passed through the rolls. The iron in the center prevents the steel from cracking when it hardens. The plates for the neck and door are fastened together with conical steel-headed bolts.

There is a Sargent time lock and one of Kitzredges best combination locks for the door. The time lock is so arranged that in case of breakage of the works, they can be operated by electricity until the time for the clock-work to release the bolt. The bolts and usual bright portions are nickel plated, and the whole finish is very ornamental. This is the first job of iron work for the Treasury done in this city. Assistant Treasurer N. W. Spaulding, who is a mechanic himself and can appreciate good work, is abundantly satisfied with this job, knowing it will compare favorably with that done by mechanics anywhere. Most of the work of this character has heretofore been done in Boston.

Another vault just like this is now being done by these Works for the Los Angeles bank and two or three more are promised. Mr. Rix's work has been highly commended by all those who have seen it. The fitting of the joints and the general workmanship is very creditable. By the way, it may be mentioned as a matter of interest that the representative of the PRESS who went to see this vault had the pleasure of seeing a pile of silver in bags amounting to twenty-four million dollars; and a pile of gold which summed up the magnificent amount of forty-six millions of dollars. Besides this there were ten millions of dollars worth of gold certificates and other such trifles which made up an aggregate of about eighty-six millions of dollars. Mr. Rix's new vault was necessary to hold more of the wealth that is coming in.

The Patton Concentrator.

The Patton concentrator has been very much improved of late, and is operated by a new motion. The machine is quite simple, and cannot get out of order easily, so that any one may set it up and run it. Mr. Patton has some 25 of them at work in various places, and he says they are giving satisfaction. There is this peculiarity about this machine. It saves all the floured quicksilver and any amalgam that may escape from the battery separate from the concentrations. This is done by a copper plate on the bottom.

When the stuff comes on to the machine it is three-quarters of an inch lower than the sulphuret discharge. This means the inventor gets the amalgam and sulphurets separate. The sulphurets discharge at the lower end, tailings at the lower end, and mercury and amalgam are held on the plate. Mr. Patton is building these concentrators at the Etna works, in this city, and those who may desire to see one in operation should call on him. The cut in our advertising columns shows the form of the concentrator. It only weighs 600 pounds, and is easily transported. Some of those who have used them say they will pay for themselves in quicksilver alone, even if there are no sulphurets in the ore. The motion of the machine is very much like that of an ordinary miner's pan.

The flow of water from the Suto Tunnel is 49,683,800 standard gallons per day.

Cost of Mining Copper.

The cost of mining copper ore of course comes within wide limits, the fluctuations being due to price of labor, nature of the ground, and, above all, to the outlay for prospecting and dead work, growing, as it does, at a rapid rate when large blocks of unproductive ground are traversed. The introduction of high explosives and power drilling machinery has not alone cheapened the cost of dead work and ore extraction, but has also rendered it possible to do more rapid work. The Lake Superior region is the center of the copper mining industry in this country. The managers of the Atlantic mine there estimate that, with drills, six men can stope 60 fathoms per month, at a cost of \$10, while with the same number of men by hand work only 25 to 27 fathoms can be stoped, at a cost of \$17.

At the Copper Falls the cost for drifting with power drills per foot was \$9.08, against \$10.33 by hand; for sinking, \$10.86 and \$11.65 respectively; and for stoping, per fathom, \$13.99 and \$14 respectively. According to a statement made by the officers of the Conglomerate Mining Co., the total cost of drifting by hand is \$11.43 per foot, while it is \$11.17 per foot by drills, drifts opened by the latter, however, being carried along in larger dimensions, so that when passing through copper-bearing ground there is an additional advantage of \$1.80 per foot, not counting the fact that in power drilling the advance is more than twice as fast as in hand drilling. The cost of hoisting, breaking, selecting, etc., has been decreased by handling large quantities. The following figures of the cost of treatment of rock (exclusive of mining and surface expenses) in different mines at various periods will aid in forming an estimate of the capacity of Lake Superior mines to produce copper cheaply:

MINE.	Years.	Quantity of ore treated.	Cost of breaking, hoisting, stamping, washing, etc., per ton.
Copper Falls.....	1862	19,752	\$1.12
Allouez.....	1881	63,362	1.07
Allouez.....	1882	97,232	.98
Atlantic.....	1875	100,000	.93
Atlantic.....	1881	176,055	.48
Atlantic.....	1882	139,800	.42
Quincy.....	1870	55,027	2.15
Quincy.....	1880	84,426	.79
Oscoda.....	1881	160,880	.92
Central.....	1881	20,549	.72
Central.....	1882	18,639	.88

The cost of transportation to the smelting works varies with locality. Lake freight to Detroit is from \$3.50 to \$4 per ton. The charge for refining is about \$11 per ton. The bulk of the copper is shipped by water to Buffalo, and by rail to Eastern markets, at from \$6 to \$8 per ton of 2,000 pounds.

At the Globe copper mine, in Arizona, the cost of production is from 9 to 9.25 cents per pound. It is thought that the Calumet & Hecla (Lake Superior) can lay down copper at the railroad for 7 cents per pound. The following table will be of interest as showing the cost of Lake Superior copper produced in 1882, when full details were obtainable. The figures, by the way, show a reduction in cost from previous years.

MINE.	Product in 1882.	Cost of production—cts. per lb.	Per ct.
Quincy.....	5,685,796	9.50	3.21
Oscoda.....	4,176,782	12.97	...
Atlantic.....	2,631,708	13.80	0.69
Central.....	1,353,557	14.76	2.20
Allouez.....	1,683,557	15.04	0.87
Franklin.....	3,264,120	13.00	1.10
Pewabic.....	1,482,665	17.00	1.00

ECLECTIC MANUAL OF PHONOGRAPHY.—Elias Longley, of Cincinnati, Ohio, has issued a new work with this title, for the price of seventy-five cents. The demand for short-hand writers is increasing, as they are being employed in railroad offices, insurance offices and various branches of business. The new manual is intended for the use of all desirous of acquiring the art of writing short-hand rapidly.

SUPERINTENDENT McALLISTER, who has had charge of the Auburn mine, near Dun Glen, for a year past, has been called East to the company's headquarters at Chicago. He says there is not much hope of resuming work on the mine this season.

GEORGE CADWALADER, who was the principal lawyer for the farmers in the farmers' debris suits died this week.

Hold on a Bit.

You who are thinking of making a break for the *Cœur d'Alene* country, keep cool, restrain your ardor and listen a moment to a little cautionary advice as we gather it from certain old campaigners, some of whom have participated in all the notable mining stampedes that have occurred in California from the first down to the present day: Went to Gold Bluff in the spring of '51; to Kern River in the summer of '54; to Frazier River in '58; to Washoe in '60; to White Pine in '69 and to Snake River in '71, to say nothing of minor excitements occurring intermediate between these more widespread and sweeping stampedes. Now this is what these old timers tell us—they give it as their opinion that not one man in ten who has joined in these senseless rushes has ever reaped any benefit from them, while thousands of their victims, besides losing their time and money have in other respects been seriously injured, not a few of them wholly ruined thereby. They have been the cause too of much loss of life—more a good deal than most persons suppose. Few know or have ever paused to think how many men have perished in these wild crusades searching after gold in remote localities. Embarking in frail crafts some have suffered shipwreck on their way to or back from Gold Bluff; some overcome with exposure and fatigue laid down and died in the gloomy woods of British Columbia. Some were swept to death over the rapids or engulfed in the treacherous eddies of the Fraser. Of the more adventurous not a few battling with Indians on the distant frontiers, while others vainly struggling sank under their burdens in the snows of the Sierra or perished from thirst far out on the deserts, where their uncollared bones lie bleaching to this day. Such being the results that have so generally attended these mining crazes, it might be well for those who entertain thoughts of immigration to *Cœur d'Alene* to ponder the matter well before concluding to light out for that delectable region. This new sensation may turn out another delusion and a snare. We detect about it the same earmarks that characterized all the earlier movements. It is being engineered in the interests of the same classes, so conspicuous in bringing these old-time frauds into notice. The unthinking masses are being excited by the same means and methods employed for booming Washoe, White Pine and Frazier rivers. And it is curious to note how very similar are the conditions under which this business of awakening public interest and en- thusing the masses is being accomplished. In every instance have these pretended mineral discoveries been made late in the summer or along in the autumn, to be reported just as the winter is coming on. At first, and so long as there was any danger of an immigration being started up prematurely, these reports were of mild and dubious tenor. As the winter has advanced and the snow falling to such depth that no prospecting could be done, the accounts from the diggings have been more encouraging, and, so keeping on, have, by the time spring arrives, swollen into the most Munchausen proportions, creating wide spread excitement and starting a heavy emigration towards the new *El Dorado*.

And this is exactly what has, and is now being, done in the case of the *Cœur d'Alene* mines. Last fall the accounts that reached us from that quarter were not very assuring—a mere after-glow—a faint boreal light, as it were, in the north. Later, this aurora began to flicker and gleam with a more lively flame, and now it shoots aloft a beacon to attract and dazzle with its brightness. How these publicans, traders, locators of mining claims and townsites, habernating up there in this gore of Northern Idaho, came to find out that there was so much gold in these gulches at a time when the ground was frozen deep and covered up under ten feet of snow, is not explained. Probably, however, by the aid of Aladdin's lamp, which reveals treas-

ures hidden away in caves and other obscure places. How it happened that these rich gulches escaped the vigilance of former explorers, the country having been thoroughly prospected years ago, is another mystery. There are, indeed, so many suspicious circumstances connected with this whole business, that we feel warranted in putting the mining public on their guard against it.

Whatever there may be in that country, not much can be lost by waiting a little. If the mines there are as rich and extensive as some represent, there will be room and gold enough for all, even for those who arrive a little late. If the diggings are poor and of limited extent, as others contend, those who have not already

likely to be early and largely tenanted. Many a poor fellow who goes there will probably remain. If he fails to obtain the great object of his pilgrimage to that dismal region, he will receive at least such rites of sepulture as are common in pioneer mining camps—his grave a rude hole in the ground, his shroud a gray blanket.

To all working-men in California our advice is, remain where you are. The haying season is at hand, to be followed by the grain harvest. Of both there will be such crops to be cut and gathered as have never before been grown in the State. The ingathering season will be long, and labor will be in demand at good prices. Parties employed by the farmers in California

sufficient grain to support its population, a considerable quantity is imported from Russia, Hungary and the United States. Quite extensive shipments of fine flours are made to Greece from Austria-Hungary and the United States.

On Rock Drills—No. 2.

(Written for the Press by GEO. J. SPOON, C. E., 415 California St., San Francisco.)

Description of the Brandt Drill.

The Brandt drill is shown in the engraving accompanying this article, one view showing it at work and the other showing details. The drilling machine proper consists of the piston *A* and the cylinder *B*, which latter is firmly connected to the socket piece *C*. The head of the piston carries the drill-rod *D*. By introducing water under pressure into the cylinder, the same and with it the drill-bit is pressed against and into the rock. The annular space *E* is constantly filled with water. The rotary motion is imparted by two small hydraulic engines, *D* and *E*, coupled together under 90°, with differential pistons, and attached to socket *C*. Their valve motion is so arranged that the right hand steers the left hand one, and *vice versa*. The engines actuate by cranks a shaft carrying a worm. This worm gears with a worm-wheel, *H*, swinging loose upon the cylinder *R*. The wheel *H* is solid with the outside cylindrical shell *P*, and connected at its other end with the piston *O*, which carries the drill rod. The wheel being turned turns the shell, and thereby the drill. The drill rod consists of a number of longer and shorter tubular sections with flat screws at either end; they are quickly joined and disjoined by a wrench, much quicker than the change of drills in the percussion drills. The drill bit has three, four or five point or teeth, carefully hardened, which protrude a little beyond its edge, making the largest diameter of the bit two and three-fourths inches, while the cylindrical part of the bit is only two and a half inches in diameter. This, however, varies with the different character of the rock. Contrary to the deafening noise of the percussion drills, this drill works perfectly noiseless, only the crushing of the rock under the enormous pressure of the drill being audible.

Drill Column.

The drill is supported by a column *N*. This is constructed after the principle of the hydraulic press, with a differential plunger-piston. By admitting the pressure water into the interior, the plunger-head is forced out against the side of the heading, and the shaft is thus set fast. The plunger can be withdrawn by means of a two-way cock and the pressure upon the annular space between the piston and cylinder-shell. The column and drills are carried on a small-wheeled truck, and are counterbalanced, so as to be in equilibrium when the column is not fixed. The machines can be moved up and down on the columns, and can be swung around the same horizontally. It is kept in position by a clamp. The hind part of the machine,

which remains unmoved and stable during the work, is connected with the clamp by a hinge. By means of a nut the machine can be turned on this hinge, and so assume any desired position. The column can be swung around parallel to the line of the heading, so as to occupy less room, when advancing or retiring. The working of the machine is carried on by means of the valve chest *B*, which contains a single stop cock, *Z*, admitting the pressure water simultaneously into the branch pipe leading to each of the hydraulic engines *D* and *E*, and a two-way cock for producing the forward or backward movement of the drill-plunger.

By opening this cock the pressure water is admitted through the pipe, *U*, to the rear of the plunger, where it acts upon the full area of the plunger, to force the drill-bit into the rock. On closing the cocks the drill is drawn back by the pressure acting constantly upon the small annular space in front of the plunger-piston. By

SECTIONAL VIEW OF THE BRANDT HYDRAULIC ROCK DRILL.

gone had, of course, better stay away from them altogether. It is argued on all hands that not much can be done there before the first or the middle of June, the snow being too deep to admit of work, or even prospecting, being done to advantage for several weeks to come. When the snow begins to melt the streams are swollen into torrents, delaying operations for another two or three weeks along the ravines and gulches where the deposits, if any there be, are mostly located.

Meantime the cost of living in the district will be great, there being also trouble in reaching it, as the streams are high and the mountains blockaded with snow. Owing to uncertainty as to the size of the claims and the practice of locating them over and over, that seems there to prevail, contentions and fights and bloodshed is inevitable. Already shooting on this account has begun, and the traditional graveyard having been started in the camp, is

are apt to receive good treatment, and never fail to get their wages. For all who want work here there will be then abundant opportunities. That the man who embraces these opportunities will fare better and find himself richer at the end of the summer than he who seeks fortune in the *Cœur d'Alene* or any other mines, we verily believe. Of course a certain class of excitable men will go anyhow, but thoughtful consideration will be best for all.

MILLING IN GREECE.—The wandering class of people in Greece and Turkey, as well as many other of the poorer class, still use the ancient hand-mill for crushing the corn, wheat or barley. The coarsed parts are sifted out through a common tin or wire sieve. The flour is simply mixed with water and baked in hot ashes between iron plates. There are now a great number of wind flour mills, a few ship mills and some steam mills. As Greece does not raise

ENGINEERING NOTES.

A Railway Through the Sahara.

In a lecture delivered to the Lower Rhenish Architects' and Engineers' Association, Herr Juttner lately gave some interesting particulars on French railway projects for the northwest of Africa. The Sahara railway is intended to connect Algiers with Timbuctoo; but the obstacles in the way of its successful accomplishment are serious, the construction of the 1,700 miles of railway being impeded by the climate, the scarcity of water, the dangers arising from sandstorms and the hostility of the natives. The temperature of the Sahara is especially trying from the fact that the nights are extremely cold. For the purpose of supplying water an extensive system of water-pipes is spoken of, which would cost about \$8,000 a mile; but it is also remarked that there are in the Sahara underground water courses, which, coming into view at certain spots, form oases. It is therefore argued that artesian borings would probably be successful, so that the pipe communication alluded to could probably be confined to various points.

The only detailed plans in existence regarding the Sahara line are those which affect the portion in Algeria about 250 miles in length. Of the remaining 1,450 miles, about one-half would seem to have been roughly planned on the information of travelers, while the projects for the remainder of the line are of a vague character, being founded on unreliable information. The cost is estimated at \$80,000,000, and the whole scheme is based on the material assistance of the French government in its execution. The calculations of profit are partly founded upon the gain to be derived from the importation of salt into the Soudan, where it is worth from 18 to 26 cents per pound. The company working the line would have a monopoly for the sale of salt, and a revenue of \$2,000,000 is looked for from this source. The import of various necessities and the export of products of the Soudan are relied upon to supplement this return in an important degree, the rates being based on charges of three cents per ton per mile for most classes of goods, and 1½ cents per passenger per mile.

THE GRANDEST STAIRWAY IN THE WORLD.—The Calvario Hill, just west of the city of Caracas, the scene of a battle between the Spaniards and the patriots in June, 1821, has been made into a beautiful park. Going up the mount is what I believe to be the most magnificent stairway in the world. I have never seen anything approaching it in stateliness and beauty in Europe. It is of sandstone, 100 feet wide and 80 feet high. The park cost \$2,000,000. The crest is 600 feet higher than the level of the city, and is surmounted by a statue of the "Great President," Guzman Blanco, the "illustrious American," as he is called, who has done so much to pacify and build up the country. He may have made money during this working, but the people certainly have the improvements. He is worth about \$15,000,000.

HOW LONG WOULD IT TAKE TO FILL THE SAHARA?—In view of the recent project to fill up the Desert of Sahara by connecting it with the Mediterranean sea, a correspondent of the *Scientific American* writes to that journal inclosing a few figures, the results of some calculations. According to the latter it would require 4,000 years for the waters from the Mediterranean to fill the valley of the Jordan, which is 1,000 feet below the former, the water to flow through a passage 100 feet wide by 25 feet deep, with a velocity of 4 miles an hour. With a channel 100 times this capacity it is possible, he says, to limit the period of filling to 40 years. At the same rate it would take 40,000 years to fill up the Caspian sea to the sea level, and thousands of years to fill up the Sahara.

A TWELVE MILLION BRIDGE.—It is reported from Russia that the question is being agitated of connecting Constat and Oranienbaum by a bridge at a cost of \$12,000,000. The structure will be erected under the supervision of engineers appointed by the Russian Government. It will rest upon granite pillars fixed by the caisson method, each of them protected from the action of the waves during the prevalence of southwest winds by an angular wall-like guard of stone. The bridge will be about 5 miles in length, and it is expected to be completed in the year 1889. When finished it will consist of two parts—a railway and a foot-bridge—and will be illuminated by the electric light.

THE MESSINA TUNNEL.—From recent observations it is said that there is great probability that the geological structure of the bottom of the straits of Messina is favorable to the excavation of the proposed tunnel. As yet, however, the data secured are not very elaborate, and of course the conclusions based on them cannot be precise.

A PRIZE FOR ELECTRICIANS.—The Italian government has determined to offer, on the occasion of the opening of the Turin Exhibition, a prize of 10,000 francs for the most practical process for the transmission of electricity.

USEFUL INFORMATION.

To Get Rid of Clinkers.

EDITORS PRESS:—In the last number of your journal it is stated that the only way of getting rid of the troublesome clinker is to knock it off with a hammer. Some years ago I had a large office stove which had become almost filled with clinkers. I made a good fire in it, let the clinkers get thoroughly hot, and then placed on the top of the fire and in contact with the clinker, half a dozen oyster shells. The fire was then allowed to run down, and the clinker was found to be so soft that it could be scraped or cut off with a shovel, just like soft cheese. A few lumps of lime, I presume, would have answered the same purpose, the lime in the oyster shells acting as a flux. C. W., New York, April 16, 1881.

AN ELASTIC LACQUER.—*Van Nostrand's Magazine* says a lacquer of great elasticity, perfectly supple, and not liable to peel off, is made in the following manner: About 120 pounds of oil varnish are heated in one vessel and 33 pounds of quicklime are put into 22 pounds of water in another. As soon as the lime causes an effervescence, 55 pounds of melted India-rubber are added. This mixture is stirred and then poured into the vessel of hot varnish. The whole is instantly stirred so that the ingredients may become thoroughly incorporated. Straining and cooling complete the process. When required for use it is thinned with the necessary quantity of varnish, and applied hot or cold to wood, iron, walls, water-proof cloth, paper, etc.

BURNING WATER GAS.—From abroad comes the news that an American now residing there has succeeded in perfecting a contrivance that is apparently destined to widely extend the sphere of usefulness of water gas. He fits an ordinary fish-tail burner with a refractory attachment, made luminous by the combustion of ordinary non-carburized water gas, and has found, by a series of carefully conducted photometrical observations, that the water gas will give 1.8 times the light of coal gas in the same kind of burner and for the same volume. It is likely, therefore, that in the future water gas will be distributed for fuel and for lighting purposes simultaneously.

WOVEN BELTS.—An advocate of cotton belts says: "Woven belts give and take. This is in the nature of a woven material. When first put on, they require 'taking up' once or twice more than leather. The stretch is approximately six per cent, as against four per cent in leather; but, once well at work, they give less trouble, as there is but one joint to look after. If put on really tight enough, this stretching is minimized to a great extent. Users are afraid to overstrain the belt, but the extraordinary result attained by certain experiments made as to tensile strain, shows the impossibility of breaking a belt under fair conditions."

TO PREVENT SCRATCHING MATCHES ON PAINT. A correspondent in Florida, of *New Remedies*, speaks of the defacement of paint by the inadvertent or headless scratching of matches, says that he has observed that when one mark has been made others follow rapidly. To effectually prevent this, rub the spot with flannel saturated with any liquid vaseline. "After that people may try to strike their matches there as much as they like, they will neither get a light nor injure the paint," and most singular, the petroleum causes the existing mark to soon disappear, at least when it occurs on dark paint.

INDELIBLE STAMPING INK.—E. Johanson, of St. Petersburg, gives the following formula for a convenient ink for marking clothing by means of a stamp: Twenty-two parts of carbonate of soda are dissolved in 85 parts of glycerine, and triturated with 20 parts of gum arabic. In a small flask are dissolved 11 parts nitrate of silver in 20 parts of official water of ammonia. The two solutions are then mixed, and heated to boiling. After the liquid has acquired a dark color, 10 parts of Venetian turpentine are stirred into it. The quantity of glycerine may be varied to suit the size of the letters. After stamping, expose to the sun or apply a hot iron.

A GOLD COLORED SURFACE ON BRASS may be produced with a liquid prepared by boiling together for about 15 minutes: 4 parts of caustic soda, 4 parts of milk sugar, and 100 parts of water, to which 4 parts of a concentrated solution of sulphate of copper should then be added with constant stirring. The mixture is then cooled to 167° Fahr., and the well-cleaned articles are immersed in it for a short time, when the gold color will appear. A longer immersion results in the formation of a bluish-green tint, and a still more prolonged action causes the formation of iridescent colors.

TO GLUE LEATHER TO IRON, paint the iron with some kind of lead color, say white lead and lampblack. When dry cover with a cement made as follows: Take the best glue, soak it in cold water till soft, then dissolve it in vinegar with a moderate heat; then add one-third of its bulk of white pine turpentine, thoroughly mixed, and by means of the vinegar make it of the proper consistency to be spread with a

brush, and apply it while hot; draw the leather on quickly and press it tightly in place. If a pulley, draw the leather around as tightly as possible, lap and clamp.

TO MAKE YELLOW OILED CLOTHING.—For a solution for making the yellow oiled clothing that teamsters wear instead of rubber coats and pants: Dissolve 1 ounce of beeswax in 1 pint of the best boiled linseed oil over a gentle fire, applying when cold with a piece of rag, rubbing it well in, and afterwards hanging up to dry, which will take about four days. The same solution also answers for making aprons that are used in slaughter-houses. They are soft and pliable, black on one side, and show the canvas color on other side, but will not let water soak through.

TO EAT BACON WITHOUT SMOKEING.—Curing bacon by hanging it up, after proper salting, in a tobacco barn, is recommended by a Kentucky correspondent as making a sweet and perfect cure, with no necessity for smoking, and leaving no taste of tobacco in the meat. It is probable that the aroma given off by the tobacco has a mild antiseptic effect, such as that which belongs to creosote, carbolic acid, and other substances which occur in wood smoke.

PAPER SOAP.—The latest novelty in New York city is paper soap, which is mainly for the use of travelers. The sheets of paper, which are put up in the form of a small book of about three inches square, are coated with soap and said to be just as good as the regulation article, in addition to being much handier. There are fifty soap sheets in each book, costing in the aggregate about as much as an ordinary cake of soap.

PROFITABLE INVENTIONS.—The smallest invention sometimes proves the most lucrative. A San Francisco lady, inventor of a baby carriage, received \$14,000 for her patent. The paper pail, the invention of a Chicago lady, yields a large income. The gimlet-pointed screw, the idea of a little girl, has realized millions of dollars to its patentee.

TO WRITEN small articles made of copper and brass, boil them in three-quarters of a pound of cream of tartar, and one pound grain tin or any pure tin finely divided. The tin dissolves in the cream of tartar and is precipitated on the brass or copper.

GOOD HEALTH.

Magnetism as a Healing Agent.

Numerous experiments have been made for the purpose of determining the influence of magnets upon the human body. The first experiments made were conducted in Paris nearly a century ago. A man by the name of Mesmer, professed to have obtained remarkable results from the use of large magnets. The French Academy appointed a committee to investigate the matter, one member of which was the eminent Benjamin Franklin. The committee found that some effects were apparently produced by the magnets; but when the magnets were replaced by blocks of wood resembling them, the effect continued the same as before, leading them to the conclusion that the results apparently obtained from the magnets were really the work of the imagination of the patients. Numerous experiments have since been made in the same line, and some persons have claimed results from the use of magnetism; but it is by no means established that the magnet is of any remedial value whatever. Professor Charcot, of Paris, has been quoted as recommending the use of magnets, and we saw a small magnet in use in his Clinic at the Salt Petriere in Paris; but on making inquiries respecting the matter, we learned that he had no faith whatever in the remedial efficacy of the magnet, except as it influenced the imagination of the patient. He employed it in certain cases of hysteria in which the disease was largely due to a perverted mental state. We consider of no value whatever the various forms of magnetic shields, etc., which are recommended and sold as panaceas for nearly all the diseases to which flesh is heir. If magnetism is of any use whatever as a remedial agent, it must be employed in very large quantities, and by the aid of very powerful magnets. The tiny magnets used in magnetic shields would exert less influence upon the circulation than the ordinary-sized pocket magnet carried in the vest pocket. A magnetic insole will, of course, aid in keeping the feet warm, as will insoles of any other description. —*Herald of Health*.

Pine Extract for Bathing.

It has long been recognized that the atmosphere of pine forests has an invigorating and beneficial effect upon people with weak constitutions and suffering from pulmonary disorders. At some of the watering places of Germany the very simple prescription of the physician is that the patient should spend several hours a day walking or riding through the pine wood. This simple treatment is sometimes supplemented by the taking of pine baths, and in the cases of kidney diseases and for delicate children this is claimed to be highly beneficial. The bath is prepared by simply pouring into the water

about half a tumblerful of an extract made from the fresh needles of the pine. This extract is in color and closely resembles molasses in consistency, and when poured into the bath gives the water a muddy appearance, with a slight foam on the surface. The repugnance one feels to enter into such a muddy-looking fluid is dispelled as soon as the delightful aroma which arises from the bath is inhaled.

Although there may be some doubt whether pine baths act upon the system in any other wise than as a tonic, still, as an adjunct to the daily bath, infusion of the pine extract induces a most agreeable sensation. It gives the skin a deliciously soft and silky feeling, and the effect upon the nerves is quieting. It is a matter of some surprise to us that the business of manufacturing and bottling the extract for private use and public bathing establishments has not been tried in this country, where pine forests abound so extensively. The extract, when properly bottled and securely corked, will not deteriorate for a long time, and the cost for gathering the pine needles and extracting their tarry substance would not be very great, while the demand for it would likely increase to large proportions when the public became accustomed to its use. This extract is used at the baths at Sharon, N. Y., and many other places in the United States.

A New Cure for Cancer.

Information of one more remedy alleged to possess special virtues in curing "cancer" reaches us through a correspondent from Brazil. Dr. Ignacio Alcibiades Velloso, of Recife, Pernambuco, introduced the remedy to notice, and in a communication to the *Journal de Recife* gives his experience of its use.

He states that the plant, which is popularly known by the name of the "alvelos," belongs to the Euphorbiaceae, and is indigenous to Pernambuco. He alleges that a magistrate who was suffering from epithelioma of the face, and who had returned to his estate despairing of relief, was entirely cured of his disease by the topical application of the juice of this plant. Dr. Velloso, learning this, was induced to employ the same remedy on two patients at the Hospital Pedro II—one a case of canceroid of the nose, the other of epithelioma of the lip—with the result that the first patient was "completely cured" in forty days, and the second in less than two months, "much to the surprise of the other professional men of the establishment." Such results, he thinks, justify a trial of the remedy, especially in uterine cancer.

The action of the juice of the plant, as others of the same natural order, is irritating, producing a spreading dermatitis without much pain; and the application of the cut stem or the juice of the fresh plant to the diseased part is said to result in destruction of the morbid tissue, which is replaced by healthy granulations—doing the work, in fact, of the chloride of zinc paste.

Upon this we need only remark that if the remedy really possesses the escharotic action described, there is less reason for doubting its efficacy in such localized morbid formations as those mentioned than there was for questioning the alleged virtues of other remedies, such as "condurango," which flourished for a time, but which were supposed to operate after they had been taken into the stomach. It is clear, however, that the use of the "alvelos" must be limited to the regions in which the plant grows. —*Lancet*.

ARTIFICIAL HUMAN MILK.—There are several factories in England for making artificial human milk, which is extensively used. It is made from pure cow's milk, which is first placed in a hermetically sealed boiler and heated to a temperature of 100° C. to destroy all germs. Then a digestive ferment, called pancreatine, is added, by which artificial digestion is produced. Then dilute acids are used to precipitate the excess of albumen and to bring about the same constitution as human milk. The process is too intricate for ordinary use. The product is said to produce excellent results. Thirty sick children fed on it in a public institution gained in health and weight most rapidly.

RUSH OF BLOOD TO THE HEAD.—A rush of blood to the head or face, causing a hot sensation for a moment, when not occasioned by violent exercise or mental emotions, is due to some disturbance of that portion of the nervous system which regulates the circulation of blood in the small blood vessels. Such disturbances usually accompany conditions of the system in which there has been loss of nerve tone. It is frequently present in nervous dyspepsia, and is one of the indications of the approach of the menopause, or change of life, in women.

CORPORAL PUNISHMENT.—In the opinion of the *Medical Press*, most physicians are very decidedly in favor of the total abolition of corporal punishment in schools. The editor asserts that the London University College school, which is attended by 500 boys, has been carried on from the first without corporal punishment, and is equal to any school in England with respect to discipline.

INNOCULATION FOR RABIES.—M. Pasteur and his collaborators have announced to the French Academy of Sciences the fact that, by inoculation, they can render all dogs absolutely proof against the effect of rabies, in whatever way or quantity the virus may be administered.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

SOUTH SPRING HILL.—Amador Ledger April 28: The third cleanup of this mine was made on Monday of last week, and resulted as satisfactorily as the previous run. The amount realized was \$7,000, exclusive of sulphurets. About 350 tons were passed through the mill, which makes the average yield \$20 per ton. The mill has been idle since, on account of repairing the shaft. Some of the timbers, 15 inches in diameter, were found to be rotten throughout, and the Supt., J. R. Tregloan, determined not to subject his men to the risk of working with the shaft in that condition. The mine is looking as well as ever, but having but one shaft, the mill must remain idle whilst repairing is going on.

MISCELLANEOUS.—A cleanup was made at the Tellurium mill last week, which panned out less than \$150. The battery had been running 12 days, and the expectation was that the ore would yield at least from \$6 to \$7 per ton, and at this rate the total surrender would have been from \$800 to \$1,000. The drop to \$150 put a damper upon the concern, and has led to the suspension of work, with a slim chance of again starting up in the near future. The big tunnel at Middle Bar is now in over 800 ft. A boulder of quartz was struck last week, carrying considerable sulphurets, but believed to be barren of gold.

Calaveras.

GLENCOE.—Cor. Calaveras Chronicle, April 29: W. C. Childs, our efficient mining Supt., went to the city last week where he was called on matters concerning the Con. Val. M. & M. Co. Two of the mines owned by the company are in operation, and it is reported others owned by the same company will soon be put in working order. The mines are owned by an Eastern syndicate reported to be immensely wealthy, hence there is no good reason why Glencoe should not take the lead as a first-class mining camp. Plenty of rock! Plenty of gold! Admitting the ratio to be sometimes two rocks, one gold. A report is current on our streets that D. Fairchild, the famous prospector, has purchased the McNamara ranch, for which it is said he paid \$1,500. Messrs. Menadue & Frittenbach are preparing to erect an aqueduct on their mine. The motive power will be an overshot wheel driven by water from the Mokelumne canal. The owners have several hundred tons of first-class ore on their dumps. The rock is said by old prospectors to be good—\$50 ore on an average.

WEST POINT.—The Scorpion mine is running in full blast. Mrs. B. Lufkin, one of the chief shareholders, is sojourning in town at present, watching operations. The Wide West is running, and from what I can learn they are taking out rich ore. The Henry mine, now owned by Messrs. Jenkins & Rowe, is going to commence operations in a short time. The Mr. Jenkins, who has recently been in England, will return in a few days with an English Company. The Star of the West will start up soon. Mr. Richardson is daily expected. The San Antonio is shut down at present. The citizens of this burg anticipate lively times this summer in a mining point of view.

Inyo.

DARWIN NOTES.—Inyo Independent, April 28: J. B. White informs us that work goes steadily on in the Defiance, Independence, Sterling, Modock, and other mines around Darwin, and the outlook is very promising for good results in that district this summer. Supt. Fitzgerald will start to crush ore from the Modock about the 10th of next month, and has enough on hand to keep the mill running about thirty days. The Reilly Co. have a force of men in their mines, and the mill is kept running steadily. The company will commence to ship bullion in a short time.

RICH ORE.—M. C. Lasky and John Anton came in from Chrysopolis last Sunday, bringing with them some rich ore specimens from the Carson mine. They report the vein widening as they go down, and the quality of the ore grows better as depth is attained. The ledge is now at the least calculation 24 inches in width, and assays way up in the hundreds of dollars per ton. There is every reason to believe that the Carson will turn out to be a bonanza of no small proportions.

THE NEW FURNACE.—J. W. McMurry, of Big Pine, was in Deep Spring valley during last week, perfecting arrangements to move the Montezuma furnace to its new site at Antelope springs. These springs are the first water reached after crossing the Inyos on the road to the valley. The entire furnace will be on the ground within the next ten days.

DREPP SPRING MINES.—Berry, Broder & Co., are now taking out some remarkably rich gold rock from their mine, the "Gold Coin," in Deep Spring valley. Greenly & Co. are at work upon the wagon road to the "78" mine, preparatory to hauling the ore from that and adjacent mines to the mill, now soon to be in readiness for business. The Sam Piper mine, in the same locality, continues to "horn out" surprisingly rich, in free gold.

CAPITALISTS.—A party of Eastern capitalists, we are informed, passed down the railroad this week on a tour of inspection to the mines of Darwin, Cerro Gordo, Lookout and other mining camps. They were accompanied by H. M. Yerington. This shows that our county is attracting attention from the outside world. And we predict that before the summer is over there will be prosperous times in Inyo.

GOLDEN WEDGE.—Work has been commenced in earnest on this mine—recently purchased by M. L. Cook. The Golden Wedge is situated near Bishop creek, and report says promises to become a good property. We have been promised a full description of this mine and its workings at an early day.

Nevada.

SPENCEVILLE COPPER MINE.—Nevada Transcript, April 25: County Surveyor Hartwell, who has returned from a business trip to the lower part

of the county, says work at the Spenceville mine is progressing with good results. Excellent ore is being extracted in liberal quantities. The regular force of men, including quite a number of Chinese as roasters, are kept at work. This week the Ruby Gold Mining Co. paid H. H. Kennedy, of Good-year's Bar, \$680 for the privilege of tailing into Rock creek for one year. This is the first installment paid by the Ruby Co. under the compromise entered into with Mr. Kennedy last fall.

NOTHING LIKE A MINER'S FAITH.—H. H. Hartley has been granted patents for two quartz mines in Meadow Lake district. Mr. Hartley is the man who first concluded that Meadow Lake had a great future as a mining district, and he is the only one who has stood by it through thick and thin. He says the rock contains enough gold, and that all that is needed is a process that will reduce the rebellious ore. Some men differ with him as to the ore containing gold in paying quantities. The latter say it is easily enough reduced, but that what Hartley wants is a process which will do as strange a thing as to make a turnip shed blood.

QUARTZ MINING ON THE RIDGE.—James L. Morgan, of Cherokee, was in town yesterday, and paid the Transcript office a pleasant visit. Mr. Morgan says that it will soon be determined whether the numerous quartz developments recently made in the neighborhood of his town are of material value. So far the prospects are very flattering, but not enough work has been done to show whether the deposits are very extensive. He promises to keep us posted as to future operations. The Cannonball mill just erected on Thurston Brothers' claim was started Wednesday, and ore is now being crushed.

Plumas.

MINING DISCOVERY.—Greenville Bulletin, April 23: For some days past it was known that a mining discovery of importance had been made near town, but the owner requested that nothing be said about it till further development should be made. Since the early mining days of this district it was supposed by all the old miners that a rich ledge crossed near the head of Taft ravine. This ravine comes down just east of the burying ground, and many years ago a great deal of money was taken out there by ground sluicing. Many pieces of quartz were found containing from \$60 to \$80. A great deal of float rock was picked up and good wages made pounding it out with a hand mortar. More of it was hauled away and milled. All this time search was made for the ledge from which the float was supposed to come, and in this search thousands of dollars were expended. Mr. John McIntyre says he spent over \$2000 in the search. How much John Blood spent is not known, but he had men employed for a long time and did a great deal of work. It is said by several men that Mr. Blood was so eager to find the ledge that he actually made a standing offer of \$10,000 to any persons who should find it. Not only miners, but the business men of the town became interested in the search. Many tunnels were run, bores and shafts were sunk, but the ledge was not found, and the search was given up years ago. Since the death of Mr. Blood nothing was done on the ground till lately. Mr. J. P. Hall, who did not come here till after Mr. Blood had passed away, had often heard the old miners speak of the rich rock found in the ravine, and when coming down the mountain last fall from the Ophir mine owned by him, looked over the ground where all this prospecting had been done. The location of the old tunnels could be ascertained only by the mounds of dirt, as they had all caved in but one, and this one was evidently in bedrock. Some distance down the mountain he noticed several shallow holes from which quartz had been thrown out. This led him to think that if the tunnel was in bedrock, the ledge must be between these holes and it. He examined the ground carefully, and became convinced that if a ledge was there at all it must be within 30 ft of these holes, as there were indications of bedrock at that distance. The winter storms set in soon after, and prevented prospecting till within a few days. In the meantime Mr. Hall had been quietly getting all the information he could from men who had worked on the ground, and with this his own observation had made him very familiar with its features. Last week he went to work in one of the holes mentioned, and after getting the snow shoveled out started to run a cut up the hill. Near the surface rich float-rock was found, and in a few hours he struck what he firmly believes is the long sought ledge. At the point of discovery it is seven ft wide. Surveyor Higbie has no doubt that it is a permanent ledge, and the one so much prospecting was done to find. Several of the old miners have examined the ledge, and all are firm in the same belief, several have also made proposals to buy interests in the claim, but Mr. Hall has refused to sell till he shall do more development. Mr. Hall was at one time manager of the Good Hope mine near Downville; he also owned stock in the well known Pittsburg mine, that for ten years paid dividends, sometimes as high as \$1,800 per share per month. He has means to prospect the claim thoroughly. The ground of this find adjoins the Crown Point on the west, also owned by Mr. Hall, as does also the Ophir Consolidated, into which both would run, direction and extent being maintained. The Ophir has lately been examined by several of the old miners, and is said to be looking remarkably good. This last discovery by Mr. Hall is making some excitement among mining men, and all hands join in wishing him success beyond his hopes.

ANOTHER CHISPA.—Plumas National, April 26: From Yank Hammond, who came down from Johnsonville on Thursday, we learn that Mr. L. Lannes, while at work in his claim on Jamison creek, and almost directly under the site of the old town of that name, picked up a slug of gold weighing \$123. Jamison creek has long been noted for coarse gold and some splendid specimens have been obtained there.

Sierra.

CLEANUP.—Mountain Messenger, April 26: The Bald Mt. Extension Co. cleaned up Sunday 217 ounces, result of the past week's run. Cap. Wilbourn and H. Mason were down from Red Oak, this week and report their tunnel in about 250 ft. The rock is very hard. More rich ore has been found at the Colombo, Sierra City.

Tuolumne.

SOULSBYVILLE.—Tuolumne Independent, April 28: We learn that Mr. Johns, the special agent of the company owning the Soulsbyville mine, and who made a special visit to the mine last week and thoroughly examined everything, was well pleased and

recommended active work with a full force. Since the rebuilding of the hoisting works, which unfortunately were accidentally burned down last fall, only a small force has been employed until the company's special agent could examine and report. And now, as the report is favorable, the largest force that can be profitably employed will, in a short time, be engaged in getting out the fine ore and turning it into fine gold. This will not only be profitable to owners and employees but to the entire country.

The Divoll Bonanza is booming and a large force of men is being put to work to develop the mine the same as any other first class property should be. Mr. Divoll has returned to Sonora for the purpose of Superintending in person, being an old professional and lucky pocket miner. Outside of the mammoth gold bunches the vein contains large paying quantities of milling ore. When this mine is opened as it will be under the guidance of Mr. Divoll's superior judgment, it will, in the judgment of practical miners hereabout, eclipse the celebrated Bodie Standard. Johnnie Pedro found a piece of gold weighing \$310, in new ground, on the ledge, at Brown's Flat, on Monday. The gold was almost round, and had a small piece of quartz attached.

Trinity.

RESUMED WORK.—Journal, April 8: Work has been resumed on the Brunswick mine in French gulch district, most of the stock in which is held here. Rich developments are looked for.

NEVADA.

Washoe District.

GOULD AND CURRY.—Enterprise, 26: On the 2700 level the usual progress is making in the joint Best and Belcher east drift. The drift is in fair working ground, but is very hot. The north drift from the Bonner shaft on the 1200 level has reached the south line of the Con. Virginia. At this point it will be taken by J. P. Jones and others, who will proceed to mine the California and Con. Virginia upper levels for low grade ore. From this drift the best and Belcher folks are now running a crosscut west to explore the ground on the 1200 level in that direction. There is in this part of the mine a considerable amount of ground that has never been explored, and the chances are good for finding ore in it, as the indications are very favorable.

SIERRA NEVADA.—Crosscut No. 1 west, on the 3100 level, 80 ft north of the joint Union Con. winze, is out 16 ft. At this point there were signs of water and the diamond drill was put in. The drilling from the crosscut has been considerably delayed. Some of the diamonds were lost out of the drill and they were obliged to wait until new ones could be sent for and received. West crosscut No. 2, 123 ft north of No. 1, crossed the streak of low grade ore found in the latter, and west crosscut No. 3, about 100 ft north of No. 2, has been started. It is not yet out far enough to cut the ore streak. The work of repairing and retimbering the winze between the 2300 and 2400 levels is about completed.

OPHIR.—Work is progressing on the 150, 230 and 250 levels. Ore is being extracted from the latter level, and on the others several exploring drifts have been run and some old drifts and other openings are being cleaned out. The ore is being worked at the Morgan mill, on the Carson river.

YELLOW JACKET.—Sufficient ore is being regularly extracted from the old upper levels to keep the mills on the Carson river running to their full capacity. The quality of the ore remains about the same. A considerable amount of prospecting is being done at several points in the mine.

ALTA.—The only work doing in the mine at present is that of drilling west on the 2150 level. Work has been discontinued on the east drift on this level on account of the signs of water that were encountered. As soon as they have done drilling west, the drill will be put into the east drift.

CALIFORNIA.—The east drift on the 2900 level, joint with Con. Virginia, is being pushed as rapidly as possible in ground that works very well. It is now out 100 ft, about half the distance it has to go to connect with the main north and south drift.

CHOLLAR.—The main west drift from the Combination shaft is being extended through the Chollar ground for prospecting purposes. As it is advanced it will be gradually turned to the southward. The material encountered is principally vein porphyry.

UNION CON.—West crosscut No. 1, on the 3100, is out about 23 ft. It is still in vein porphyry of about the same appearance as that in the main north and south drift. This is the only point in the mine at which work is now being done.

CON. VIRGINIA.—The joint California east drift, on the 2900 level, is being advanced at the rate of nearly 30 ft per week. It is now out 100 ft, which is about half the distance it had to go to connect with the main lateral drift.

MEXICAN.—The winze that is being sunk below the 3100 level is down 30 ft. It still continues in vein material of about the same character as that in which it was started. Work is being done at no other place in the mine.

HALE AND NORCROSS.—A west crosscut has been started at the foot of the incline on the 2800 level. It is out about 30 ft. The ground is dry, and is a mixture of quartz and porphyry. The drift will gradually be turned north.

BELCHER.—The several drifts in the old upper levels continue to yield well, and the mills are kept going. A considerable amount of prospecting is being done in different parts of the mine.

BEST AND BELCHER.—Good progress is being made in the joint Gould and Curry east drift on the 2700 level. The ground works very well, but the drift is very hot.

ANDES.—Some paying ore continues to be extracted and the prospecting drifts encounter a good deal of quartz of a promising character.

COMBINATION SHAFT.—Are now sinking below the 2800 level. At a proper depth the Cornish pump will be moved down the distance of another lift.

SAVAGE.—Work has not yet been resumed in this mine. The water tapped by the north drift on the 2600 level is slowly decreasing.

CROWN POINT.—The usual amount of ore is being extracted, and the mills on the Carson river are kept running to their full capacity.

Belmont District.

WORK PUSHED.—Belmont Courier, April 26:

Work is pushed vigorously in the Belmont mine, and the face of the drift on the 200 ft south level is in good ore. Very fine ore is now being hoisted to the surface. Messrs. Lamb and Griffin are busy prospecting in the Monitor-Belmont mine.

Columbus District.

MOUNT DIABLO.—True Fissure, April 26: But few changes of note have been developed in this mine since the date of the last report. This north crosscut from winze No. 5 has been driven 14 ft, and in the west intermediate, between the second and third levels, a south crosscut has reached a distance of 11 ft in length. An east drift is being in the intermediate, between the second and third levels, near winze No. 5. A west drift is also being driven near the same point, and is showing some good ore in the bottom of the drift. The south crosscut, from the east drift on the second level, is in 156 ft. It shows a small spot of \$60 ore. The west drift on the second level, from the crosscut near the Callison winze, has been stopped and a drift has been started west on a small streak of \$70 ore. The incline has been sunk 14 ft during the week. It is now down 87 ft below the third level.

COLUMBUS CON.—The work on the different levels is progressing with very satisfactory results. The crosscut from the fourth level has been extended a short distance in ground that is favorable for a development of ore, having a considerable quantity of vein matter in the face. Encouraging prospects continue to be found in the drift to the west from the main drift on the same level. The work in the drift to the east from the same point has been resumed and some ore of good grade is being obtained from this part of the mine. The west drift from the south crosscut on the 150 level remains inactive, as also does all operations on the first level.

Cerro Gordo District.

REPORTED STRIKE.—Walker Lake Bulletin, April 21: Another rich strike is reported on Buena Vista Mountain, in Cerro Gordo district. The ledge is said to be four ft wide and assays over 500.

Grantsville District.

PARYVENU.—Bonanza, April 26: S. G. Post has cut into a vein of ore in the Paryvenu mine that shows free gold. How extensive it will prove can only be determined by going down on it. In any camp on the coast where mining operations are being pushed vigorously and mines worked for what they contain a prospect that would make as good a showing of free gold could be sold for several thousand dollars; but, unfortunately, in Grantsville if a man had a mine from which ore could be profitably extracted in sufficient quantities to run a 100-stamp mill 50 years the ore would have to be allowed to remain in the mountain for lack of capital to properly work the mine. Reduction works cost too much money for this poor chondrier to ever dream of turning his ore into bullion at his own mill, and if he ships it to a distance it has to work over \$200 a ton before he is decently paid for his labor. About the only thing that will put life into things in this section will be the resumption of work in the Fer'd S. Van Zandt serious of mines.

Garfield District.

A MILL.—Walker Lake Bulletin, April 28: Hon. George Ernst, of Nye county, is in Garfield district laying out a site for a mill. Garfield will soon be one of the busiest districts in the State. When they get a mill in there close to the rich ore, the small st veins will be worked. Some of these veins carry an enormous proportion of silver, and wonderful returns will be received from there.

Eureka District.

ANOTHER FURNACE.—Sentinel, April 21: Steps are being taken by substantial and responsible gentlemen of Eureka to lease the old Matamoras furnace (capacity 40 tons) and run it in the reduction of custom ores. They are negotiating with a number of mine owners and superintendents with the view to have them guarantee them the ore from their mines for a reduction for a given period, six months, we believe. The Matamoras is a comparatively new furnace, belonging to Chicago parties, to whom application has been made for lease. There is good prospect of the consummation of the scheme, and it is certainly to be hoped that it will be successful. The new company proposes to reduce ore for \$10 per ton—\$2 less than anybody else will reduce it here for now. This difference in favor of the miner is practically immense. Four bits difference per day to a man who earns his living by taxing his muscles and the drip of sweat is vast, and \$2 is four times four bits. And then what a quantity of ore there is that will pay with \$2 added to its value. A careful mining Supt., who guarantees all the ore from his mines to the new smelting company, says the proposed reduction will add 300 miners to the camp. It is a big thing for the town, and a living margin for the honest miner.

Ellsworth District.

NO WORK.—Grantville Bonanza, April 26: We do not think that work will be resumed in the Mount Vernon mine, Ellsworth, in the very near future.

Mount Cory District.

THE MOUNT CORY.—Walker Lake Bulletin, April 21: The mill is now working about 50 tons of ore per day and regular weekly shipments of bullion are being made. It is reported that another rich strike has been made in the lower levels of the mine. Earl & Co's teams are now hauling about 45 tons of ore per day to the mill. There is a surplus of 500 tons in the ore-house.

Pittsburg District.

NEW CLAIM.—Battle Mountain Messenger: Thomas Cummings, an old Base Range miner, has discovered and located a mining claim near Pittsburg district, which promises to be a big find. The ledge is a large one, being 20 ft in width so far as prospected, and assays from \$75 to \$300 per ton in gold. The mine lies on the north side of Crum's canyon, and is about three miles from the Morning Star and Pittsburg Consolidated mines in Pittsburg district, and is in the same mineral belt. Mr. Cummings has succeeded in getting W. O. Mills, Jr., interested in the property, and they have made preparations to sink a shaft to the depth of 100 ft to test the ledge, and if satisfactory at that depth they will begin working the ore, of which there is an abundance on the surface. Mr. Cummings thinks they have got a bonanza, and from what others say they have certainly got a good prospect for one.

Sherman District.

MOVING QUIETLY.—Reno Gazette, April 26:

L. J. Flint, P. Bates, W. N. Coughlin and John Fitzgerald visited the mines in Sherman district yesterday, and report things to be moving along quietly but surely. At the Burke mine the ledge has been opened on the surface in several places, and shows considerable rich ore in spots. The shaft of the Stephen A. Douglass is now down 87 ft. When a depth of 100 ft is attained, a crosscut will be run from the bottom of the shaft to cut the vein. The formation through which the shaft is now passing is mineralized to some extent, indicating a near approach to the ledge. No other mines are being worked at present.

Tybo District.

ORE.—Belmont *Courier*, April 26: There is considerable ore exposed in the 2-G mine at Tybo, and it is expected that the next run will be a good and profitable one.

ARIZONA.

HUMBURG DISTRICT.—Cor. Prescott *Courier*, April 26: Old Humburg camp is to have a boom at last, which consists of a ten-stamp mill, complete. The machinery was unloaded at Maricopa a few days ago. The stamps weigh 1,000 pounds each. The engine is 40 horse-power; boiler, 100 horse-power. There is also one large Blake rock crusher. Total weight of machinery, 80,000 pounds. The name of the company operating here is the St. Louis-Avapai M. and M. Co. There are now 25 men employed in making a road from Frog-tanks to Humburg, which will be completed in about two weeks. The machinery will then be hauled to the mill site and put in place just as quick as money and mechanics can do it. The mines belonging to this company have been well prospected. There are hundreds of tons of ore on the different dumps, and particles of gold can be seen in a great many pieces of the ore. Where gold is not visible the ore prospects well. There are 17 claims, and it will take a long time to mill the ore that is in sight. There will be about 50 men employed just as soon as the mill is completed. There will also be a five-stamp mill and concentrators put up during the coming summer, about two miles above here at Farley's camp. The concentrators will be shipped to Benson for reduction. Mr. Montgomery is running his astrara on ore that pays \$50 per ton. Jones & Thompson are running their astrara on rich ore. Pete Donnelly has out several tons of choice ore that he will work soon. Farley & Co. have been running their astrara some time on ore that pays well. They will make a cleanup in about a week. West of Humburg about two miles, on Cow creek and its tributaries, ten men are placer mining and making good wages. Just over the ridge and north of Tip Top, the silver miners are happy because they are taking out lots of shipping ore that yields 300 ounces of silver per ton.

THE STARKE AND EWING MINE.—Mohave County *Miner*, April 26: This valuable claim, which was located as long ago as 1871, is the first south extension of the Fairfield mine, and lies between the Fairfield and Keystone mines, the two latter being two of the best known mines in Mohave county. The "Starke and Ewing" takes in all the ground between the two above mentioned mines, some 400 ft in length along the ledge. Although it is little more than a quarter the usual length of mining claims, it more than makes up for it in the width and extent of the ore body. Situated as it is on the hillside just north of town, the immense croppings of the vein are plainly visible from town. This property has just been purchased of John Hughes by B. Moses, for Messrs. Glyn & Co., of New York. The ore body has not yet been crosscut anywhere on the claim, but the surface indications would lead one to estimate a width of at least 10 to 20 ft. What this immense body of ore will average of course cannot be determined at present, but assays taken from the shaft range from \$43 to \$75 per ton in silver. The ore is a blue sulphuret, and from appearances could be readily milled. There is a pile of ore on the dump containing about five tons, which has been picked over two or three times by former owners and which sampled 43½ ounces to the ton at the Kingman sampling works. If the present width of ore continues for 200 or 300 ft down, and there is every indication that it will, there will be enough ore to keep a 20-stamp mill going for years. The whole ledge will pay to run through the mill just as it comes down. This is not a mine for a poor man, but it is just such a mine as a good company, prepared to properly open up and develop it, wants. With careful sorting, much of this ore would pay to ship, but we do not expect to see a pound of ore shipped. We expect that when the owners realize the vast amount of ore this little claim can produce they will at once make arrangements to have the ore milled at the mine.

IDAHO.

ANOTHER STRONG CO.—Cor. Wood River *Times*, April 25: Dr. Hayford and Dr. Yingling, both of whom are well known in your section, have just sold the Silver Vale and Golden Gate claims to the Oriental G. and S. M. Co., of Boulder, Col., whose home office is in Philadelphia, Pa. This Co. owns three good mines near Boulder, Col., but wanted something better; hence the sale. It is composed of live, substantial business men of Philadelphia, and it will no doubt begin work soon, and make things lively in and about the camp. The Vale and Gate are about two miles northwesterly of Bellevue, and about three miles southwesterly of Hailey, on the same belt as the Minnie Moore, Bullion, Mayflower, etc. Harry G. Wright, Colonel Canavan, and other Bellevueites are interested, and will look after the Co.'s interest on Wood River. The Forest creek Co. propose renewing work on their mines as soon as spring opens and one of the company can visit Wood River. This company will yet make Narrow Gauge-gulch busy as a beehive. The Wood River country is decidedly beginning to look up in the East. The late sales of the Minnie Moore and other first-class mines in Alturas county have done much toward bringing the Wood River country into notice.

PLACER MINES.—Idaho *World*, April 22: Placer miners around Centerville are at work—some running off gravel and others preparing to work their ground. Nick Hoover and Jake Kellar have been panning about two weeks in their claim below Centerville. Steve Dempsey has the water through his upper ditch, and the hydraulic is whizzing water against the bank in his claim between Henry creek and Cen-

terville. A. A. Spain has leased his ditch to a Chinese company working the Johnson claim below Henry creek. A Chinese company has been at work in Henry creek two or three weeks. Bob Williams and Jas. Smith have been running a cut the past three weeks near the quartz mill. They will work the ground by ground sluicing. Are now trying to find an old channel, and when they get into it expect to find the "yellow stuff" quite abundant. They have already struck gravel that prospects very well, and also boulders of quartz—float—that is gold-specked and will mill high. This float is all saved and will be crushed. John Lamberton, and Harry Chichesster, old Mexican war veteran, and whose arrival in California ante-dates the gold fever of '49, are making the gravel fly this side of Henry creek. When Harry's "hydraulic ram" is brought to bear, gravel will fly more furiously. McCurdy & Co. will also soon go at their diggings, near Henry creek, with a "ram."

COEUR D'ALENE NEWS.—Coeur d'Alene *Pioneer*, April 24: The opening of the present season is heralded from all quarters by the jingle of the precious metal. The high water in the main creek has restricted operations to the side gulches, but so far as heard from, pay is reported in every instance. In the 22 gulches between the mouth and head of Pritchard creek are over 2,000 men, who are sluicing and actually taking out gold by the pound. You gaze at the bottom of these boxes and the glare of gold meets the eye. With these facts the future of Eagle is indeed golden. What are the probabilities of the future? That the main creek will pay its entire length is an undisputed fact. As soon as the high water subsides, operations will be resumed, and as it is reasonably certain that the bed-rock has pay, we can confidently look forward to a boom that has heretofore been unapproached in magnitude. The thousands who are laying back awaiting developments will soon have the coveted profit thrust under their very eyes, for the dust now coming from the side gulches speak in no uncertain tone of the wealth of these hills. The recent clean-ups in Dream gulch will startle no one who has any confidence in the country.

THE STAMPEDE.—It is safe to say that the Pacific Coast or the world never saw such a stampede as has already started in for the Coeur d'Alene mines. There are now about 3,000 people scattered about in the timber on Pritchard and Eagle creeks, while at various towns, which have been selected as points of observation and approach, it is estimated not less than 15,000 people are stationed, awaiting developments and for a favorable opportunity to reach the mines, with their goods, chattels and building materials. Within two months we may expect to see our gulches teeming with the activity of 50,000 men building stores and dwellings and preparing for the tremendous boom which will follow during the summer when the great crowd comes from more distant points.

HYDRAULIC.—The old river drift which can be plainly seen on the north hillsides along Pritchard creek for a distance of six miles, will eventually be the scene of the greatest activity in placer operations. This drift is an old river deposit—apparently of the tertiary period—and prospects everywhere from a half to five cents to the pan. In California this would be considered a veritable bonanza, but here it awaits the touch of capital. The gold differs from that in the creek by being somewhat smooth and water-worn, showing a more ancient deposit. Deep gravel deposits exist in this range, and the inexhaustible amount of ground open to the hydraulic opens up a new industry the importance of which can hardly be estimated at the present time.

DREAM GULCH.—Dream gulch is only two and a half miles east of Eagle, and was struck and located in October of last year by F. M. Davis, who claims to have been guided to the spot by a vision of nuggets which settled upon his brain for three consecutive nights. It is two miles long and is located its entire length. The gulch is less than a claim wide in most parts and sufficient water is available for most of the season's run. Last week 63 ounces were cleaned up after a three day's run on the Webfoot claim, and a second run of two days resulted in the recovery of 60 ounces of coarse dust. The total value of the gold was \$2,000, which represented five days' work for 20 men—or one day's work for five men—an average of \$500 per day to the man. Last Thursday 94 ounces were obtained from a run of 36 hours. An area of bedrock 25x100 ft was cleaned in obtaining the result stated above. Bedrock averages 15 ft in depth and is a shaly slate. The surface dirt is a gravel held in a matrix of dull red clay. The Webfoot company comprises Messrs. Laird, Davis, Roy and Ebbert, who own two claims in the gulch. Considerable development work has been done on the Webfoot—a reservoir having been constructed and preparations being made to put in a hydraulic which can be done at very little expense. With a large reservoir work can be carried on the entire season. Frank Reed and Alonzo Lowe own No. 1, adjoining the Webfoot. They have a force of men at work opening up the claim and there is every reason to believe that it is just as good as the Webfoot. A drain ditch is being run to bedrock and sluices are already in position. Several small side gulches are tributary to Dream, and in all of these dirt—from grass-roots to bedrock—prospects well on the crude shovel. The colors are, as a rule, very coarse and of a dull rusty cast. The formation is shaly slate and porphyry and the bedrock is from 15 to 50 ft deep. A quartz lode has recently been discovered near the head of the creek which is said to be a marvel in richness. The discoveries have kept the matter very quiet but enough has leaked out for us to say that the camp will have a quartz revelation from Dream gulch which will astonish the pioneers.

In McCormick gulch active work in the sluices was begun last Friday. Claims are changing hands at a lively rate. Sales are being recorded daily. Dream gulch is determined to eclipse her former record. Sunday's run at the Webfoot netted 70 ozs. It is reported that the Reeder claim, just above the "Widow," was jumped last week and re-located. The gold from Beaver is of a finer quality than any yet found in the creek. Its value is \$19. In Missoula gulch extensive preparations are under way for a summer's run. The gulch is already netted by the sluice box and tail race. Raven is excited over a mammoth ledge recently uncovered in its vicinity. The find is of the same character as the New Comstock on Eagle river. On the Eureka claim, in Butte gulch, 12 ozs. were cleaned up in a day's run.

Missoula gulch sent in to-day 7 ozs. from the French boys' claim. Preparations are in progress for sluicing the bar diggings just above Eagle. A reservoir is being constructed so that work can be carried on during the entire season. Messrs. Henderson & Porter have a lease on the Gelatt claim, at the mouth of Dream gulch. They have put six men to work, and yesterday got their boxes in place preparatory to sluicing. On the tops of the highest hills between Eagle and Murrayville huge wash boulders are found, which clearly indicate the extent of the wash which covers the entire country on the north side of Pritchard creek. The snow on the south hillsides is nearly gone, and prospectors are roaming in their glory in search of the precious leads. Look out for something big and rich too. It is sure to be found, and at no distant day either. In nearly every side gulch great preparations are being made to take advantage of the high water. Much of the saw-mill product is being used for sluice boxes, and all are jubilant over the prospects. The channel has nowhere been found on Pritchard creek. It is the experience of old placer miners, however, that where the rimrock pays largely, a corresponding increase can be looked for in the channel. The led-rock has been found to pay on both sides, and that the channel will be far richer than either side, is a reasonable conclusion.

MONTANA.

MINES NEAR HELENA.—Independent, April 26: One of the famous clusters of bonanzas that are achieving such celebrity in the vicinity of Helena, is the A. M. Holter lead in Jefferson county. The Elkhorn Co. are now vigorously developing this lead as well as milling the product extracted. About a year ago the Elkhorn Company was organized and put up a ten stamp chloridizing mill upon the lead. The former wet crushing mill which had been erected had not been able to save over fifty per cent of the silver, and hence had not been a success. A marked improvement at once resulted, the main shaft is now down upon the lead over 300 ft. and near the bottom of it, an east and west level has been pushed along the lead to a distance of sixty ft. each way. The vein is about six ft. in width in these levels, and the ore body averages about 80 ounces in silver to the ton and a small percentage in gold. The shaft has been run down to water level and the owners are now putting in a large Knowles pump and will be sinking again in a few days. At water level the ore increased in value about twenty ounces to the ton, and the vein at the bottom of the shaft shows an increased width as well as richness, being seven feet wide at that point. The mill is now crushing regularly twelve tons of ore per day, and it is expected to increase the amount to fifteen tons as soon as it gets into good running shape. The gross product saved is about \$80 in silver to the ton, and the expense of mining and milling the ore about \$20, leaving a handsome profit of some \$60 per ton or \$720 per day, as the present net yield. It is expected that the large pump now being placed in the mine will drain it to a depth of 1,000 ft. and if the shaft and levels continue to develop a vein as wide and as rich as now exists, the ten stamp mill will give place to one of 20 or perhaps 30 stamps, and the present yield per day will be doubled or trebled. The company are working day and night shifts in running the levels and sinking the main shaft, and their large force of men in the mill and mine are all under the supervision of their efficient Supt., J. O. Kilburn. It is the purpose of the company to thoroughly develop the mine, and they have enough ore already in sight to run their present mill for two years. The fortunate owners evidently have one of the finest mining properties in the territory. The success of the Elkhorn Co. is but another illustration of the immense mining boom now existing in this portion of Montana. Mr. Holter justly regards quartz mining as in its infancy here. All around us developments are going on, particularly in Ten Mile district. It is a fact that five leads within less than 20 miles of Helena are now yielding between twelve and fifteen thousand dollars per day in bullion. The following estimates are based upon information derived from the highest sources as far as obtainable and are substantially correct: Yield per day. Helena Mining & Reduction Co., (at Wickes,) \$6,000; Gloster, \$2,000; Gregory, \$2,000; Drum Lumber, (estimated,) \$3,000; A. M. Holter, on Elkhorn mine, \$500. Total \$13,900. If we add to this the yield from a number of less noted mines in close proximity to the city, and include the placer yields, the revenues from cattle and sheep, saying nothing of agriculture, it is safe to say that not less than 20,000 dollars per day is regularly added to our money circulation in this city, the greater portion of which remains with us. Taking into consideration the immense developments in quartz mining going on around us, and the fact that almost all of our large mines like the Drum Lumber are increasing their mill capacity, it is probable that before twelve months this yield will be increased to \$50,000 per day or \$1,500,000 per month! Our readers can well understand from these figures the secret of the Helena boom—and why those who have the best means of knowing sanguinely expect that our city will have a population of 20,000 before two years.

NEW MEXICO.

NOTES.—Silver City *Enterprise*, April 18: The coal strike at Fleming is attracting some attention. Much activity is exhibited at Pinos Altos; an era of prosperity is in store for the camp. Work is progressing on many of the claims in Steele Rock district. Ore shipments to the Benson smelter will shortly commence. Many men are gulch mining on Gold gulch, southwest of the city. For the first time in a number of years a sufficient quantity of water for sluicing purposes is in the gulch. Rich quartz ledges have also been discovered in the vicinity of the placer claims. The Jerry Boyle and Bonnie Jean claims are the only two upon which work is being done in the Shakespeare district. The five-stamp pony mill of Peter Wagner started on the 13th inst., and has been kept in motion since that date. Mr. Wagner has put in a Rapid ore concentrator which is also running to perfection. Pinos Altos is fast coming out and will in all probability be one of the liveliest mining camps of the territory in a few months. Smith and Christian are the fortunate discoverers of the coal beds at Fleming. An analysis of the coal gives 35 per cent carbon, and it is said to be coking coal. George Ceassidy will commence work with a force of men upon a group of claims adjoining

the old H. no. 9 mine in Hanover district, on Monday. The same character of copper ore as that of the old Hanover mine, which is owned by King Catron of Santa Fe, is known to exist upon Ceassidy's claims, and he intends mining it and disposing of the same to the Socorro and Denning smelters. The one-fourth interest owned by James Cunningham in the Billard's Peak coal strike, was purchased on Saturday last by Hon. H. H. Whitehill and Joseph Bell, of this city. Development work is rapidly progressing on this property with satisfactory results. Apache camp, near Eureka, is developing some important mineral discoveries of late. The Datsy, owned by Dennison and Schachman, promises to become one of the leading properties of Grant county. It shows an immense body of ore of good grade. About 125 tons of shipping ore have been already produced and from what is in sight a steady product of several tons daily can be maintained without difficulty and in doing development work only. A carload will shortly be shipped to the Benson smelter, that will by sample tests already made, average upwards of \$700 per ton. The Dandy is the name of a new strike in Apache camp, and is owned by Wm. Moore. Where first struck at the surface the ore, which is from six to eight inches in width returned from 800 to 1,300 ounces per ton. Aside from this rich streak there is in the same vein between three and four ft. of ore that will average from 40 to 50 ounces. The silver at Apache camp is found as a chloride, usually in a gangue of decomposed siliceous iron and is readily susceptible of treatment by the ordinary milling process. Some lead is also found, but where it exists in quantity it can easily be assorted out of the dry class of ore, the latter class predominating as a rule. A good future is assured this promising young camp when once its prospects are developed to the point of continual production.

WORK COMMENCED.—Silver City *Enterprise*, April 25: Work was again commenced on the Old Man mine at Fleming, on Monday morning last, and we understand will be continued without interruption during the summer. The force at work at the present time is small, but will be increased as the work demands it. The property is said to be looking better at the present time than it ever did in the past. Work will be commenced in a few days upon a group of claims near Fleming, recently sold by Black & Mullen to Mr. Anthony, of Denver. Mack Bros. & Powell are reported to have struck a three and a half foot vein of lead carbonate ore in their property in Hanover gulch that is looking well. From average tests recently made the ore is found to run 60 ounces in silver. The property is reported to be the best in that vicinity if not in the county. Georgetown is very dull just now, but its prolific mineral resources render a revival of business there and a prosperous future as certain as fate. Kingston looks prosperous and wears the general aspect of a mining camp whose people have no doubts as to its permanent prosperity. The recent staving up of the smelter has rendered business of all kinds more brisk. Men who were disappointed in obtaining situations at the "blow-in" found employment as teamsters in hauling ore from the King mine at \$2.35 per day. Contractor Gregg is going to construct a new road from Kingston to Lake Valley. Owners of claims in Hanover Gulch and other points in the vicinity of Georgetown, have nearly all completed this year's assessment work. Development work is being done on some of the claims. Business is quite lively at Lake Valley and yet there are a good many idle men there.

UTAH.

REVIEW.—Salt Lake *Tribune*, April 23: The week has been an exceedingly quiet one in the mining business. The storms continued, the roads are still blocked by snow and mud, and the canyons are all difficult and many impossible of passage, as far as transport of ore is concerned. The receipts of bullion in this city for the week ending April 23d, inclusive, amounted to \$74,464.91. There were no receipts of ore, the President, from which most of such receipts come, being unable to ship on account of the roads. The week before the receipts in this city were \$108,987.98 of bullion. The shipments from this city for the week ending the 19th instant, inclusive, were 2,022,677 pounds. The receipts from the Horn Silver for the week were ten cars of bullion—\$30,000. Total shipments to date, reckoned by our daily reports, \$657,000. We hear nothing more of the raid made by New York journals on the Horn Silver, and no more gloomy predictions in regard to its dividend capacity. The Ontario sent during the week 28 bars of bullion, valued at \$34,764.91. Total product for this year to date, \$532,846.08. The Ontario is in a highly prosperous condition, and has abundant ore resources. The product of Hanauer smelter for the week was five cars of bullion—\$9,700. There are getting to be very large accumulations of ore in the bins at Alta, and when the tramway begins to operate in the spring, it will bring down a silvery stream that will materially enlarge the current production. At Bingham the old stand-bys are producing well, and will continue to do so. Some very promising new mines will also be heard from favorably in ore output the present season. The week has been one of storms and difficulties, but the spring preparations go on about as usual. The miners who wintered in the city have quite generally gone again to the hills, and will not be seen till next fall. They will soon begin to be heard from in the ore and bullion product.

NEW PLACER DISTRICT.—Park *Mining Record* April 26: A meeting of miners was held at Lambert's cabin, on the South Fork of the Provo river, on Tuesday, April 22, 1884, for the purpose of forming a placer mining district. It was resolved that the district be named the South Fork Mining district. The following boundaries were adopted: Commencing at the mouth of what is known as Bridge Hollow; thence running southerly up said hollow to the dividing line between Uintah and Wasatch counties; thence northerly along the said dividing line to the junction of Summit and Wasatch counties; thence down the north fork of the main river to the point of beginning—all situated in Wasatch county, Territory of Utah. The same being about twenty miles in an easterly direction from Heber City, the county seat of Wasatch county, Utah. Thos. P. Potts was unanimously elected Recorder of said district.

PATTEN'S**CONCENTRATOR AND AMALGAMATOR COMBINED.**

This machine requires less power, less care or attention, and is less liable to get out of repair than any conc entra tor now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

The undersigned is now located at the Etna Iron Works, 217 to 221 Fremont street, where he is building the above machines and prepared to fill orders, and guarantee them to do all that is claimed. Estimates given and orders promptly filled for all kinds of mining machinery.

C. W. PATTEN, 217 Fremont Street, S. F.

DOWNIE**EUCALYPTUS****BOILER SCALE****Preventive and Remover.**

(Patented May 8, 1883.)

In use in 1,000 Boilers on Steamboats, Locomotives, Mills, Mines, Foundries, etc., in California. An

Mining Share Market.

During some portions of the week the market has been in an excited state. The sales of Hale & Norcross went up into the thousands of shares. Our stock tables show the variations in this and the other Comstock mines, most of which participated in the movement. The most startling news of the moment is that of the closing down of the Grand Central mine at Tombstone, on the 30th. Shortly after shutting down, a newspaper representative interviewed Supt. Gage as to the cause of the stoppage. He stated that for the past four months the ore bodies above the water line had been growing poorer in grade until battery samples would not average \$20 per ton. Last month the loss to the owners was \$23,000. No work could be done below the water level for the reason that the pumps could not control the water. At the present rate of wages—\$4 per day—the mine could not pay expenses, and the company would not run at a loss any longer. The Miners' Union here positively refuse to work at \$3 per day—the proposed reduction—and unless a compromise can be effected, the probabilities are the mine will remain closed until new pumps are put in, which will be in about six months. It is said that both the Contention and Toughnut will close in a few days.

Bullion Shipments.

Hanauer, April 21, \$3,850; Horn Silver, 22, \$9,000; Hanauer, 24, \$2,100; Ontario, 22, \$14,832; Horn Silver, 22, \$20,832; Ontario, 23, \$5,177; Stormont, 25, \$3,690; Hanauer, 25, \$3,850; Horn Silver, 25, \$6,000; Ontario, 25, \$5,156; Ontario, 26, \$5,276; Horn Silver, 26, \$3,000.

Subscription Price Reduced.

The MINING AND SCIENTIFIC PRESS, Dewey & Co., publishers, San Francisco, is the representative mining journal of the Pacific coast, and worthy the support of all whose interest it steadily advances. The new terms are very low, and within the reach of the poor, struggling prospector as well as rich mine owner—\$3 per annum, paid for in advance.—*Mountain Messenger, Donoville.*

Stock and Grain Land.

Parties wishing to purchase good stock raising lands unaffected by severe droughts, will do well to address the undersigned. The lands can be purchased cheap, in lots from 100 to 2,000 acres. It is partly low table and rolling land, partly clear and level. Good for vine and fruit raising. Will raise vegetables and all kinds of grain. Crops certain every year. Near town and a \$10,000 public school house. Price, \$3 to \$5 per acre. Good local market for fruit, vegetables, grain, poultry and dairy produce. Address the proprietor,

EDWARD FRISBIE,
Anderson, Santa Co., Cal.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

JARED C. HOAG—California.
J. J. BARTLETT—Sacramento county.
A. S. DENNIS—San Mateo county.

B. W. CROWLEY—Fresno and Tulare counties.
J. W. RILEY—Merced and Stanislaus counties.
Geo. McDOWELL—El Dorado and Amador counties.
WM. PARSONS.

New Incorporation.

The following company has been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

RUSSELL REDUCTION AND M. Co., April 25. Object: To purchase own and work gold mines, to purchase work subunit or other rebellious ones in the immediate vicinity of West Point by the Russell process, at a point on the east bank of Bear creek, Calaveras county. Capital stock, \$10,000,000, in 100,000 shares of \$100 each. Directors, E. F. Russell, W. J. Shives, Wm. H. Jeffers, J. Morizio, San Francisco, and E. T. Barber, Oakland.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Works Company, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below costs, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

The necessity of practicing economy is keenly felt by many at this time, and it is fortunate that there are places where one can buy a good article at a low price. The California Furniture Manufacturing Company, 228 Bush street, are selling bedroom sets from twenty-four dollars upwards, and other furniture at equally low prices. Their goods are first-class.

Lost Papers.

If any subscriber fails to receive this paper promptly, after making due notice at the Postoffice, he is urgently requested to notify this office by letter, that we may send the missing papers, and, if possible, guard against further irregularities.

REMITTANCES to this office should be made by postal order or registered letter, when practicable. Cost of postal order, for \$15 or less, 10 cts.; for registered letter, in addition to regular postage (at 3 cts. per half ounce), 10 cts.

MINING SHAREHOLDERS' DIRECTORY.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Dewey & Co.'s Scientific Press Patent Agency.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

DEWEY & CO., Patent Agents.

No. 252 Market St. Elevator, 12 Front St., S. F. Telephone No. 658.

A. T. DEWEY. W. B. EWER. GEO. H. STRONG.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 35 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or rift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this rift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veinlets of quartz specked with ore. This mine is 1 1/2 miles northerly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize equalled by none—yes, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

AN EASY BINDER.—A. T. Dewey's Patent Elastic Binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price, size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co's. journals, Harper's Weekly and Scientific American, 85 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. Send to this office for illustrated circular. Agents wanted.

MRS. ADCOCK, having just returned from the East, begs to offer to the public some of the FINEST GOODS ever imported to this coast, at prices lower than ever before. An inspection is solicited.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.

FOR WEEK ENDING APRIL 22, 1884.

297,219.—LAD BOARD.—A. L. Anthony, Placerville, Cal.
297,127.—HEADER AND THRASHER.—S. L. Gaines, Stockton, Cal.
297,258.—APPARATUS FOR MAKING RINGS, COUPLING LINKS, ETC.—Silas Harris, S. F.
297,412.—PISTOL HANDLE.—J. C. Kellon, S. F.
297,470.—KEY TAG.—F. A. Knox, Woodland, Cal.
297,452.—PAWL FOR CABLE GRIP LEVERS.—Root & Tucker, S. F.
297,468.—TANK FOR WINDMILLS.—H. R. Stevens, Los Angeles.
297,317.—LAMP BRACKET.—A. Thurber, Concord, Cal.
297,327.—ANIMAL SHEARS.—W. F. Wickenden, San Luis Obispo, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific Coast Inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through DEWEY & CO.'S SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

ANIMAL SHEARS.—Wm. F. Wickenden, San Luis Obispo Co. No. 297,327. Dated April 22, 1884. This relates to that class of shears known as sheep-shears in which the blades are forced together against the resistance of a spring at their base where they are united and under the influence of which they are separated when the pressure is relieved. The invention consists in a new and useful means or device for holding its blades wider apart to afford facility in grinding them. This class of shears is made so that the blades remain normally open to provide for their cutting action in closing; but they are not open far enough to permit grinding. The present custom to accomplish a wider separation is to insert a cross-stick between their shanks. In this operation the difficulty of contending with a strong spring renders the insertion of the stick a matter of some trouble; but the greatest drawback is that while grinding the blades, the stick is liable to become loosened, and the blades, being released, come together and frequently cut the hand of the operator. The object of the invention is to provide a brace which is capable of easy adjustment and which will not slip.

TWO-WHEELED VEHICLE. James S. Creighton and Joseph Taylor, Smith's Flat, El Dorado Co., Cal. No. 295,361. Dated March 18, 1884. This is another device intended to overcome the "jogging" motion commonly imparted to two-wheeled vehicles by the movement of the horse. The inventors think that the best spring for these vehicles is the "platform spring," as it forms a better foundation than the ordinary elliptic springs. A different connection of the platform spring with the shafts of the body has to be made. They dispense with the usual cross-spring in front and connect the side-spring with the cross bar of the shaft by means of connecting strips. These furnish support, and a shackle-connection admits of their moving with the shafts without affecting the springs. This makes the conveyance easy riding, the jogging motion being avoided.

GATE OR VALVE.—Phillip Giovanni. No. 295,998. Dated April 1, 1884. This invention relates to certain improvements in valves of that description known as "straightway" valves or gates, and it consists of two disks having their outer faces formed to close against corresponding seats in the passage, and having double inclines upon their inner sides, either concave or convex, together with inwardly projecting lugs, which fit corresponding depressions in a central lug. This block has double-inclined surfaces to correspond with and act upon the inclines of the valves in closing or opening the same, and it is moved by a screw thread upon the stem or spindle.

KNIFE AND PEN HOLDER.—Isaac Phillips, Silver City, Idaho. No. 296,054. Dated April 1, 1884. This consists of an implement, the handle of which is an ordinary knife handle fitted with blades, and having in its back near one end a chamber in which a short pen and pen holder lie, the latter being pivoted to the handle in such a manner as to enable it to be opened out with its pen so that the handle of the knife will then form for it the staff when the implement is used in writing. A hinged casing or cover is adapted to receive the pen and its holder when lying within the chamber, whereby dust is kept out when the implement is carried in the pocket.

DOOR AND PANEL WORK.—Wm. N. Miller, Oakland, No. 296,035. Dated April 1, 1884. This invention relates to certain improvements in the manufacture of door and panel work. It has been difficult to construct good, substantial doors from soft and brittle woods, such as Oregon cedar and California redwood, on ac-

count of the difficulty in making good, substantial joints, and also because the edges or angles are easily bruised or broken. In this invention the stiles and rails are united by hard-wood dowel pins to form a joint. Narrow strips of hard wood are secured on the edges of the doors.

SAFETY CAR TRUCK.—Samuel Brown, S. F. No. 297,031. Dated April 15, 1884. This invention relates to that class of safety car trucks in which a suitable guard on the truck engaging with the rail on the road-bed prevents the car from jumping the track. The patent covers improvements on a former invention. The improvement consists in the means by which the safety clamp or guard is connected with the truck, and the construction and arrangement of the parts. The object of the invention is to attach the clamp or guard to the truck in the simplest, strongest and most direct manner.

TWO WHEELED VEHICLE. Wm. T. Goodman, Fulton, Sonoma Co., Cal. No. 296,049. Dated April 15, 1884. This is an invention for preventing the rocking motion imparted to these vehicles by the joggling of the horse. The improvements consist in the arrangement and connection of springs, the means for mounting the body thereon, and a novel connection between the springs, axle and shaft. In this cart the body may move readily independent of the springs to a certain degree. On account of the character of the springs themselves and the manner in which the body is hung, the vehicle is an easy riding one.

FAUCET.—Hugo Mattulath, S. F., assignor to Security Package Co. No. 296,031. Dated April 1, 1884. This is a screw-faucet, having a valve moving within it to close or open the outlet, a wheel and chambered sleeve fitting the exterior of the body and a screw cap, having smaller threads than those in the valve-stem, fits over the end of the faucet body and prevents the valves from being screwed entirely out. By this invention the faucet is first screwed on until properly sealed. The sleeve is then turned until the discharge-nozzle stands in the proper position.

GREEN CORN CUTTING MACHINE.—George A. Roberts, Walla Walla, W. T. No. 296,066. Dated April 1, 1884. This machine is one designed to cut green corn from the cob, or roasting ear, for canning and other purposes and known as "Green Corn Cutting Machine." It consists in a combination of devices, in which an expanding annular knife operates in conjunction with an impaling bar.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Intelligent Boy Wanted

To work in a photograph gallery. Satisfactory references required. Fourteen to eighteen years of age preferred. Wages moderate at first. A country lad or one who lives at home in the city preferred. Apply at this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

A Good Chance for City Real Estate Investment.

The following property in San Francisco will be sold at low rates exceedingly favorable to purchasers who wish to buy for safe and profitable investment.

IN THE MAP, No. 3.—Northwest corner of Aztec street and California avenue, 3 lots, Nos. 84, 86 and 88. On the southwest corner of Aztec street and California avenue, 3 lots, Nos. 98, 100, 102, 104 and 106. On the west side of California avenue, between Hope and Tomasa streets, lot No. 1123. On the east side of Shakespear street, between Hope and Isabel streets, lot No. 1411. On the south side of California avenue, bounded on the other three sides by Bradford, Standish and Mayflower streets, 20 lots comprising a whole block, Nos. 1189 to 1209 inclusive.

IN THE MAP, No. 1.—Southeast corner of Islais Creek Channel and Chace street, 1 lot, Nos. 1969, 1970, 1971 and 1972. Northeast corner of Chace and Freedom streets, 5 lots, Nos. 1955, 1956, 1957, 1958 and 1959. South side of Napoleon street east from Bigg street, 2 lots, Nos. 2527 and 2528. North side of Tulare street east from Bigg street, 2 lots, Nos. 2543 and 2544.

Also 2 lots, Nos. 82 and 84, Oakland Homestead Association, situated near Lake Merritt, and on the easterly road to Piedmont, near the northwesterly limits of East Oakland. They are 50 feet wide by 100 feet deep, with extra land and frontage in one.

The owners themselves offer the above lots to actual purchasers at bedrock prices, and believe that no other property can be bought in the vicinity for immediate use or for investment on nearly as favorable terms.

Apply to, or address the office of this paper.

Adel's Patent Spring Shaft Driving Cart.

The Spring Shaft does away with the disagreeable motion of the horse, and the open seat affords easy and safe access from the rear. It costs less to ship, is Light and Stylish and easy riding.

Three men with Adel's Grain Elevator pile up in warehouse, or field, 1,500 sacks in a day. Address:

W. T. ADEL,
City Carriage Factory, San Jose, Cal.

SPECULATORS and CAPITALISTS, READ THIS!

I know where there are immense deposits of Coal, worth millions of dollars. I need from \$2,000 to \$10,000, or more, to LOCATE, ENTER and IMPROVE said Coal Lands, much of which is upon Government Land. Any person having the money mentioned to invest, can make arrangements with the advertiser to go out with him and see with his own eyes the immense quantity and value of said Coal Lands. I am fully convinced that any party investing in said Coal Lands can, in less than two years, realize at least \$100 for every dollar invested. Any person possessing the requisite means and meaning "business," can address for two weeks, appointing time and place for interview,

A. B. "COAL,"
Care E. R. Robinson, P. O. Box 1474, San Francisco, Cal.
N. B.—The advertiser can show the very highest testimonials concerning integrity and business capacity, and can give good Real Estate Security for as much as \$5,000.

To Architects and Builders.

Valuable Vault for Sale at a Bargain

A contractor has a thoroughly burglar-proof vault for sale. Dimensions, 4½x5 ft.; height, 7 ft. in the clear; weight, about 6,000 lbs. In perfect order throughout. Double doors inside. Single burglar-proof outside door, 1½ inch steel and iron combined. The bolt work is of superior and first-class quality in all respects, there being no better on this coast. Can be examined at any time. Write for further information. Address P. H., box 2361, S. F. P. O., or inquire at this office.

MACBETH'S

-PATENT-

STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting.

On account of their great lightness and the form of the arms, they absorb less power than any other pulley.

They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, NOV. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,

For the Mather Lane Spinning Co. (Limited),
[Signed:] RICHARD T. MARSH,
Managing Director.

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

St. Louis, Mo., Sept. 23, 1883.

Messrs. Adolphus Meier & Co.—GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER-BUSCH BREWING ASS'N.

OFFICE OF Supt. of ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 24, we respectfully inform you that the three boilers built under your patents, under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being firmly prevented thereby, and the boilers kept in prime condition.

(Signed): BRAUCKE.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE
ever invented for the service of Prospectors and
others requiring the use of a Horse Power; possessing all
the requirements of a first-class hoist and affording means
for the continuous operation of a Pump or Blower without
interfering with a hoisting apparatus.

It is made entirely of Iron; no piece weighs
over 250 pounds. At the ordinary speed of a horse a
1,000-pound bucket of ore may be raised 120 feet per
minute. The hoisting drum is under the complete control
of the man at the shaft, and is capable of carrying 500
feet of five-eighths steel rope. The cost of erection is
slight, as two men in half a day can easily put it in place
ready for work.

While this power is more particularly for mining pur-
poses, it is equally adapted to all other uses where animal
power is required. SEND FOR CIRCULAR.

**JENKINS PATENT VALVES.****Gate, Globe, Angle, Check and Safety.**

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gate Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers.—\$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical minor can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "unsuccessfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious

writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements, Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 1/2 mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by

DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver, Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

CLARENDON HOUSE,

SAN FRANCISCO, SATURDAY, MAY 10, 1884.

VOLUME XLVIII
Number 19.

Standard Time.

The accompanying map, designed to make plain the standard time now adopted by all the railway companies of the United States, was prepared by Rand, McNally & Co, the well-known map publishers of Chicago. Heretofore the railroad trains have been run under fifty-three different kinds of time; the number is now reduced to five, as follows: Inter-colonial, embracing Nova Scotia and New Brunswick; Eastern, embracing the New England States;

time of the Greenwich Observatory, London, England, and as the longitude in which their roads were situated was so many times fifteen degrees westward from Greenwich, they made their standard of time that many hours slower than Greenwich time. Hence the 60th degree of longitude is four hours slower than Greenwich time; the 75th, five hours slower; the 90th, six hours; the 105th, seven hours; and the 120th, eight hours—thus making five different standards between the Atlantic and Pacific oceans. These five standards are shown on the map in

minutes and seconds between the solar time of those towns and the standard time:

M. S.	MOUNTAIN TIME.
5 4	slower than Deadwood, D. T.
16 56	slower than Bismarck, D. T.
22 50	faster than Fort Benton, M. T.
27 46	faster than Virginia City, M. T.
1 12	slower than Cheyenne, W. T.
27 26	faster than Salt Lake City, Utah.
11 27-15	slower than Denver, Col.
5 4	faster than Leadville, Col.
4 40	faster than Santa Fe, N. M.
23 40	faster than Tucson, Ari.
24 44	faster than Prescott, Ari.

New Miner's Pick.

Dock E. W. Taylor, who has been mining and prospecting in the State for a good many years, has invented, and applied for a patent on a peculiar miner's pick. The head has sockets formed in opposite sides to receive the points, which may be removed at will. There is also a socket for the handle, with wedges at the inner end or base, by which to fix the handle in place. The inner ends of the points are formed so as to fit and wedge into the sockets in the head.

MAP SHOWING THE DIFFERENT DIVISIONS OF STANDARD TIME.

New York, Pennsylvania and the States south of Pennsylvania; Central, including Illinois, Ohio, Indiana, Missouri and the States north and south of them; Mountain, comprising the roads west of the Missouri river in the mountains; and Pacific, embracing the lines on the Pacific coast. Could we have printed the maps in five colors the divisions would be better shown, but the shading renders them sufficiently distinct for our purpose. The time in which the earth makes a revolution was long ago divided into twenty-four parts known as hours, and in measuring distances around the earth from east to west the circumference of the globe has been divided into 360 parts, or degrees of longitude. The surface of the earth travels, therefore, as many degrees in one hour as 24 is contained in 360, which is 15. Hence the difference in time between each succeeding 15 degrees of longitude, faster toward the east and slower towards the west.

The railroad officials of the continent decided to adopt as their standard of regulation the

the order mentioned at the top of the map.

The 90th meridian, on which Central time is based, is nine minutes slower than Chicago solar time. The 75th meridian, which gives Eastern time, is one hour faster than Central time, or four minutes slower than New York City solar time. Inter-colonial time, being based upon the 60th meridian, is two hours faster than Central time. Mountain time, which is based upon the 105th meridian, is one hour slower than Central time. Pacific time, based upon the 120th meridian, is two hours slower than Central time.

The several meridians are indicated upon the map, as well as the territory included in the different divisions. The irregularity in the boundaries is caused by the various roads wishing to adopt as their standard the time of the meridian nearest to which the greater number of their lines are situated.

We are on this coast more particularly interested in the Mountain and Pacific standards. The following tables show the difference in

1 23-15	slower than Chihuahua, Mex.
20 52	faster than Guaymas, Mex.

PACIFIC TIME.	
12 0	faster than Olympia, W. T.
9 50	faster than Portland, Or.
14 40	slower than Boise City, Idaho.
1 40	slower than Virginia City, Nev.
9 37	faster than San Francisco, Cal.
55 14	faster than Sacramento, Cal.

THE MECHANICS' FAIR.—The Board of Managers have resolved on some changes in the Pavilion which will afford increased space for exhibits. Many machinery exhibits were crowded out last year. It has been decided to take half of the garden and add it to the main floor. J. H. Gilmore, Superintendent for so many years, again enters on his duties next Monday, and promises, on account of the favorable indications of the season, that this fair in the character of its exhibits shall be equal to any preceding one. The fair this year will close on September 6th, thus allowing exhibitors to also appear at the State Fair at Sacramento.

At the bottom of each socket is an incline which narrows this part of the socket, so as to cause the shank of the pick arm to wedge firmly into place, and seat themselves by the stroke.

An angular hole is made through the head, cutting the diaphragm between the uniting ends of the shanks transversely to them and in the side opposite the incline. A wedge or key is driven into this opening, when it is desired to force the shanks out of the sockets. The opening or socket for the handle is made somewhat wider at the bottom or inner end than at the outer end, and has wedge-shaped projections, which enter the end of the handle when it is driven home and expanded in the socket, so as to retain it firmly in place. From the handle-socket to the edges of the point sockets are concave curved edges, which are also sharpened to an edge and these serve to cut or break roots when the pick sinks so deep that they strike. The whole device makes it easy to renew or sharpen the points when necessary, and to retain the handle firmly in place.

CORRESPONDENCE.

We cannot, unendorsed, opinions of correspondents.—Eds.

The New Copper Assay.

[Written for the Press, by C. H. AARON.]

Where assays are "few and far between" it is not convenient to keep a standard solution for volumetric determination. I find that the new assay of copper, by means of potassium zanthate, may be made gravimetrically.

The solution is to be prepared as heretofore directed for the volumetric assay, and the copper precipitated by a slight excess of potassium zanthate. The precipitate is to be filtered out and washed, first with water and then with alcohol, until the drippings no longer become turbid on addition of water; it then dries readily on the water-bath, and contains 33 per cent of copper.

This agrees with the formula $2\text{CuO}, \text{C}_4\text{H}_5\text{O}, 2\text{C}_2\text{S}_2$ being a basic zanthate containing, theoretically, 32.95 per cent of copper.

If the precipitate is washed with hot water only, the drying is almost interminable, and it is difficult to bring it above 32 per cent copper.

The potassium zanthate, by long keeping, may become slightly alkaline, and then produces a precipitate which is rather red or brown than yellow. It is only necessary, in this case, to use a sufficient excess of ammonia in the solution. The precipitate, if not yellow at first, soon becomes so.

In the case of cobalt being present, I find that the separation of the copper by precipitation with zinc is doubtful. Zinc precipitates a part of the cobalt from neutral or slightly acid solutions. It will therefore be better to use iron, or the copper (and other metals) may be separated by means of hydrogen sulphide, or the process by sodium hyposulphite may be used when the solution is suitable; the precipitated copper sulphide, or sub sulphide, being redissolved and determined by the zanthate method, either volumetrically or gravimetrically.

The Comfort of Miners.

EDITORS PRESS:—It seems to be generally considered by most mining superintendents that a hired man is something analogous to a mule, that no labor ought to fatigue him; that no hardship will injure him, and so long as he gets plenty to eat and has a place to roll over he will get up good as new. A little reflection and observation will show that this is all a mistake; even a mule will get stiff and rheumatic by long and continued exposure, and will not "get down into his collar" as willingly as one better cared for.

A sound, active and healthy man is better able to work and give value received for his wages, than one who has the rheumatism in his shoulders, or the lumbago in his back, or who is continually choked up with a cold. Miners as a rule are very appreciative of anything done for their comfort and tending to promote their health. No one employing them loses anything by obtaining their good will.

If a mine is so arranged that immediately upon coming out of the shaft, or tunnel, the men can step into a dry, warm "changing room" provided with a tank for washing, and a large stove for drying wet working clothes, men employed in such a mine will work up to a few minutes of "quitting time," while on the other hand, if upon leaving work they have to change their clothing in the blacksmith shop, or the lee side of a wood pile, subjected to drafts and chilling winds, they will begin to "taper off" an hour earlier, perhaps, than they otherwise would.

The reason is obvious, for no matter how dry and well ventilated a mine may be, the air underground is more or less stuffy and close, and hard labor in such an atmosphere induces excessive perspiration, which, if suddenly checked, is almost certain to result in colds, and some form of rheumatic lameness. Therefore, unless the miner knows he has a good warm room in which to change his wet working clothes for dry ones, he would be foolish indeed not to commence easing off an hour or more before the time approaches for quitting work. An hour lost on each man's work amounts to something in a year's time. The importance of comfortable "changing rooms" is well understood on the Comstock Lode; without them it would be impossible to get men to work the deep mines. Some of the Virginia City changing rooms are quite elaborate affairs. Many owners of wet and cold mines find it a difficult thing to keep first class miners employed more than a few weeks at a time. An examination of the facilities for changing and drying clothing might often give a good hint as to the cause. A few nails driven into the wall above the boilers, and a couple of loose boards laid across, is a very poor apology for a changing room. At the best, but a few men can change comfortably, and the choice places are usually monopolized by some "pet" or "old hand," while the majority of the men burn on one side and freeze on the other. At first sight this may seem a trivial subject, but if those interested will look into the matter as the writer has, they may see something in it. In conclusion, take as good care of your men as you do of your pet horse; see that they are well cared for and you will be more than repaid by increased service.

CHAS. L. LANG.

Sonora, Tuolumne Co., Cal., April 20th, 1884.

Metallurgy of Nickel.

The recognition of nickel as an element dates no further back than the year 1751, when the Swedish mineralogist so far separated it from its combinations as to ascertain some of its properties and justify him in describing it as an element. It had before that time been found as a troublesome residue, but was supposed to be a mixture of cobalt and copper with arsenic. According to Bergman, Hiérne was the first to write of "kupfer-nickel," in a work upon minerals published in Sweden, in the year 1694. It was not only obscure, but was troublesome and thought to be destructive of copper.

Being generally in close association with cobalt, this troublesome substance was left as a residue or by-product when cobalt ores were treated to obtain the oxide of cobalt for staining glass or producing a blue color on porcelain. The nickel was found concentrated in the cobalt speiss left in the pots when smalt was manufactured. This speiss contained other metals, such as copper and iron, besides sulphur and arsenic. The nickel, was not therefore, in a pure state, and for a long time its valuable properties were unknown, although the impure alloy was largely utilized to make the alloy commonly known as "German Silver," "*Argent de Berlin*," "*maillechort*," or "nickel silver." The impure nickel, or nickel-bronze, thus carried with it into the nickel-silver all its noxious associates, and the quality of the product was impaired, being often hard brittle and intractable. Even one per cent. or less of arsenic was sufficient to greatly modify the physical properties of the nickel or the alloys made from it. It was difficult to free the nickel from such small quantities of impurity. It resulted that nickel was for a long series of years unknown, commercially, in a state of purity.

The scientific chemists, however, succeeded in preparing small samples of the metal sufficient to experiment with and to determine its true physical properties. The results were at first somewhat contradictory, as we should expect from our present knowledge of the sensitiveness of the metal to minute quantities of either carbon or hydrogen in combination, very much as iron is affected and its properties modified by mere traces of some of the elements. For example, Richter found that nickel oxide, strongly ignited in an earthen crucible with carbon, gave the metal in a perfectly malleable, ductile condition. When so prepared it could be hammered cold or hot into plates 1-100 of an inch in thickness, and could be drawn into wire 1-50 of an inch in diameter. The malleability of the nickel was found to be impaired by carbon or manganese. Another experimenter, Tuppitt, found that nickel reduced in the presence of carbon, in a covered charcoal crucible, and under glass, formed more or less nickel-graphite, absorbed a portion of carbon, and became less ductile than zinc. The metal so produced was brittle when cold, and was as fusible as cast iron, while the metal obtained by Richter was difficult of fusion. He also noted that nickel could be welded, but Tousté found that it welded imperfectly. Deville recognized the useful physical properties of both cobalt and nickel, such as malleability, ductility and great tenacity. He showed that these metals could be worked at a forge with the same facility as iron; that they were susceptible of being employed in the same manner, and that they were less oxidizable. The facts are important to any review of the progress of the metallurgy of nickel, particularly as it will presently be shown that the metal in a state of purity was first commercially wrought into useful objects in the United States.

The influence of nickel in its alloy with iron has been brought into special notice by reason of the mingling of these two metals in various proportions in meteorites. The occurrence together of iron ore and nickel terrestrially has already been noticed. At the New York exhibition in 1853 the nickeliferous ores and iron, in addition to those from North Carolina, were from Marquette, Michigan, and were exhibited by Mr. Thurber, of Detroit. The percentage of nickel was small, but it is stated that the forging iron made from this ore by the Catalan forge process had some remarkable properties; it contained nickel, but the percentage is not stated. It had a silvery white appearance and received and retained a high polish. It has been noted by Faraday that iron alloyed with 3 per cent of nickel has similar properties. This subject has been to a certain extent investigated by M. Boussingault, whose results did not fully sustain those of Faraday. He found that steel with from 5 to 10 or 15 per cent of nickel added would in some cases rust as freely under water as steel without nickel. He also noted that some meteorites rust more rapidly than others. Nickel does not in all cases prevent rusting. A notable exception was found with the alloy of 63 parts of steel with 37 of nickel corresponding to the composition of the supposed meteoric mass of Santa Catarina, in Brazil, which resists oxidation in a remarkable degree.

The relations of nickel to carbon have been studied experimentally by the same authority. It appears that nickel does not readily absorb carbon and acquire steel-like properties. But the extreme toughness of most meteoric iron is well-known. This fact, and the excellence of the iron made from the nickeliferous limonite of Michigan, are very suggestive and important to the producers and consumers of forging irons. Another example of association of nickel ore

and iron ore is found at Antwerp, New York, and the list of examples of such association could, no doubt, be greatly extended.

An interesting contribution to the chemistry of nickel has been made by Margaret S. Cheney and Ellen Swallow Richards, of the Massachusetts Institute of Technology, who describe a new and ready method for the estimation of nickel in pyrrhotites and mattes. In the course of a systematic series of tests it was found that phosphate of nickel is completely soluble, while phosphate of iron is almost insoluble in acetic acid in the presence of an excess of phosphate of soda. The process for the separation of the metals in analysis is based on this fact.

Messrs. Eustis and Howe, of Boston, have published a method of separating nickel and other metals by suspending iron bars in nickel-bearing slag. The nickel is described as rapidly accumulating on the iron, and finally running down and trickling from the ends of the bars.

Garnier, of Paris, points out the fact that pure nickel has great capacity for the absorption of oxygen. The pure metal, fused with access of air and poured, absorbs enough oxygen to make it brittle. If fused in a reducing atmosphere it is malleable, but the same metal carried to a red heat with access of air can be pulverized under the hammer. This can be corrected by the addition of metallic manganese, but as the corrective effects of this disappear with repeated fusions, M. Garnier prefers to use phosphorus, and finds that an addition of three thousandths leaves the nickel soft and very malleable. His method of introducing the phosphorus is to first make an alloy of nickel containing about six per cent of phosphorus. This is then added in the proper proportions.

The refining of nickel and cobalt was commenced in the United States, at Philadelphia, as early as the year 1846, by Prof. James C. Booth, of Philadelphia. Ores from the Lancaster Gap mine, and some from other sources, were worked there by Professor Booth and his associates. Later, as already mentioned, Mr. Joseph Wharton purchased the works and established the nickel industry at Camden, where it has since been carried forward, using chiefly the sulphureted ore of Lancaster Gap, previously described. This ore, which contains from 1½ to 2 per cent of nickel, is enriched at the mine by a preliminary smelting into a matte containing 10 per cent or more of the metal. For a long time the ordinary nickel of commerce was produced and was used chiefly at the United States Mint for the subsidiary small coins. Mr. Wharton, not being content with the production of impure nickel, early commenced experimenting to determine whether nickel could not be produced in a pure and malleable condition, susceptible of being worked in nearly the same manner as iron, and of being applied in the manufacture of various objects requiring strength of material and a substance that cannot be easily oxidized. One of his earliest experiments was to take the somewhat spongy mass got by reduction of the oxide of nickel, and, after heating it to full redness, to work it under a steam hammer into a bar.

In 1873 Mr. Wharton sent to the Vienna Exposition a sample of nickel in the form of axles and axle bearings, and at the exhibition in Philadelphia in 1876, he exhibited a remarkable series of objects made of wrought nickel, such as bars, rods, a cube, a horseshoe magnet and magnetic needles of forged nickel. These did not excite the interest to which they were entitled as a remarkable advance in the working of this little known metal. The exhibit did not cause much comment, and it was not specially described or reported upon, except by the judges who reported the exhibit to the Commission as worthy of an award, in the following terms: "A fine collection of nickel ores from Lancaster county, Pennsylvania, with nickel matte, metallic nickel in grains and cubes, and manufactured nickel, both cast and wrought; nickel magnets and magnetic needles, cast cobalt, electro-plating with nickel and cobalt, and salts and oxides of both these metals; the whole showing a remarkable degree of progress in their metallurgical treatment."

Some of the same objects formed of wrought nickel were sent over to Paris two years later, and were exhibited in the American section in 1878. There, as in Philadelphia, they did not at first excite any surprise or receive any special attention. Very few persons realized what the objects really were, and that they were very different from alloys of nickel. In fact, very few chemists had ever seen nickel. Pure nickel was a rarity, just as samples of iridium or thallium are to-day. It was not strange, therefore, that the expert chemists and metallurgists of Europe on the international jury showed some incredulity and surprise when whole ingots and forged bars of metal and numerous finished articles of pure wrought nickel, without alloy, were offered for their inspection. These articles, not differing greatly in their appearance from the higher grades of nickel alloys, or from electro-nickel objects, were at first passed by without comment. No previous exhibition had been so rich in exhibits of the use of nickel and in the products from them. The influx of the pure carbonated and oxidized ores from New Caledonia had greatly stimulated the nickel industry in Europe, and had improved the quality of the alloys of nickel. New companies had been formed to manufacture nickel-silver and to produce nickel from these superior ores, at a lower cost than had before been possible.

(CONTINUED NEXT WEEK.)

Cœur d'Alene Mining Laws.

Enacted June 7, 1883.

SECTION 1. All locations on lodes or veins of quartz to conform to the U. S. Laws of May 10, 1872, as near as practicable, viz., 1,500 feet long by 600 feet wide.

SEC. 2. Placer mining claimants shall be allowed twenty acres located so as the length of the claim shall not exceed eighty rods.

SEC. 3. Each location shall be represented by the locator or his authorized agent in locating and recording.

SEC. 4. No person shall be restricted to one claim. Miners may locate one claim on any stream or gulch where ground is vacant, but no person shall be allowed to locate more than one claim on the same stream or gulch.

This section shall not prohibit any from bolding claims acquired by purchase.

SEC. 5. Claimants shall have one year from the first of January succeeding the date of location, to work their first annual assessment, which will be one hundred dollars each year thereafter. Claims shall be represented by twenty dollars worth of work each month after the first of June, until the first of November after the first year's assessment. Furthermore, all claims shall be considered laid over from the first of November to the first of June each season. Assessment work may comprehend all necessary work, such as building roads or trails, building houses, or any improvements needed in opening or working the claim.

Miners shall be allowed five dollars per day on assessment labor.

SEC. 6. Claimants shall be required to record their claims on the district records, within fifteen days from the date of location.

SEC. 7. The oldest or first claimant shall have the first privilege of water, but shall not prohibit others from using the surplus. All claimants shall be required to return the water to the channel of the stream for the benefit of those below.

SEC. 8. Several miners may form a company for the purpose of opening and working mines, in placer claims, where such claims are contiguous, and the labor performed by said company shall represent their several claims, though the whole labor may be done on one claim.

SEC. 9. Difficulties arising between parties in this mining district, shall be settled by arbitration. Each disputant to be allowed an equal number of arbitrators, and in case a tie on decision, said arbitrators shall have the power to call an assistant.

SEC. 10. All claims located prior to the date of the adoption of these local laws, shall be respected as those made after such date.

SEC. 11. The records of the Cœur d'Alene Mining district shall be opened and kept at Eagle City, Idaho.

SEC. 12. On the written application of twelve or more miners, the Chairman shall cause three notices to be posted conspicuously, giving ten days' notice of a meeting, said notices to specify the object and business to be transacted at such meeting. To make any changes in the present laws between the first of November and the first of June the following year, shall be illegal.

SEC. 13. These laws to take effect from this date, and any laws or regulations previously enacted that conflict with these laws shall be considered repealed.

A CURIOUS FIND.—In the tunnel of the Daniel Webster mine, northeast of this city, beyond the Wells-Fargo mine, at a point over 300 feet beneath the surface, a flow of water of a strange character has been encountered. The water boils up through the floor of the tunnel, and in the light of the candles presents an almost blood-red appearance. It smells like creosote, and has a pungent, disagreeable taste. When bottled and brought out to the light of day, the water has a rich, burnt sienna color. After standing for a time, a grayish, impalpable powder is thrown down, but the color of the water remains the same. Two or three gallons of the water have been brought to town and distributed among such persons as take an interest in things of the kind. Some of the water has been sent to San Francisco for analysis, and assays will be made of the sediment deposited by it. A bottle of the water kept in the sun for several days shows no alteration in color, and presents a clear, bright appearance of some tincture.—*Virginia Enterprise*.

TAKES A WIDER RANGE.—To-day Hugh Lamb, for so many years foreman of the old bonanza mines, will assume the position and duties of foreman of all the north end mines—Ophir, Mexican, Union Consolidated and Sierra Nevada—filling the place of R. M. Ballard, who recently went East to take up his permanent residence. As Mr. Lamb still remains foreman of the California and Consolidated Virginia, this gives him quite an extensive beat. However, he is tough as a huckskin string, and will be equal to the requirements. As work is in progress at only a few points, travel will be the principal labor called for.—*Enterprise*.

RED INK is made by taking two ounces best Brazil wood, one-half ounce pulverized alum, one-half ounce crystals of bitartrate of potassa, and sixteen ounces of distilled water. Boil down to one-half and strain. Then dissolve in it one-half ounce gum arabic, and add one and one-half drachms cochineal, dissolve in one and one-half ounces alcohol of specific gravity .839.

MECHANICAL PROGRESS.

Wire Rope and its Management.

Two kinds of wire rope are manufactured. The most pliable variety contains 19 wires in the strand, and is generally used for hoisting and running rope. The ropes with 12 wires and 7 wires in the strand are stiffer, and are better adapted for standing rope, guys and rigging. Ropes are made up to three inches in diameter, both of iron and steel, upon special application.

For safe working load allow one-fifth to one-seventh of the ultimate strength, according to speed, so as to get good wear from the rope. When substituting wire rope for hemp rope, it is good economy to allow for the former the same weight per foot which experience has approved for the latter.

Wire rope is as pliable as new hemp rope of the same strength; the former will therefore run over the same sized sheaves and pulleys as the latter. But the greater the diameter of the sheaves, pulleys or drums, the longer wire rope will last. In the construction of machinery for wire rope it will be found good economy to make the drums and sheaves as large as possible.

Experience has demonstrated that the wear increases with the speed. It is, therefore, better to increase the load than the speed.

Wire rope is manufactured either with a wire or a hemp center. The latter is more pliable than the former, and will wear better where there is short bending.

Wire rope must not be coiled or uncoiled like hemp rope. When mounted on a reel, the latter should be mounted on a spindle or flat turn-table to pay off the rope. When forwarded in a small coil without reel, roll it over the ground like a wheel, and run off the rope in that way. All untwisting or kinking must be avoided.

To preserve wire rope, apply raw linseed oil with a piece of sheepskin, wool inside; or mix the oil with equal parts of Spanish brown or lamp black. To give the mixture body, add some sawdust.

In no case should galvanized rope be used for running rope. One day's use scrapes off the coating of zinc, and rusting proceeds with twice the rapidity.

The grooves of cast iron pulleys and sheaves should be filled with well seasoned blocks of hard wood set on end, to be renewed when worn out. This end wood will save wear and give increased adhesion. The smaller pulleys and rollers which support the ropes on inclined planes should be constructed on the same plan. When large sheaves run with very great velocity, the grooves should be lined with leather, set on end, or with India rubber. This is done in the case of all sheaves used in the transmission of power between distant points by means of ropes, which frequently run at the rate of 4,000 feet per minute.

Steel ropes are to a certain extent taking the place of iron ropes, where it is a special object to combine lightness with strength.

But in substituting a steel rope for an iron running rope, the object in view should be to gain an increased wear from the rope rather than to reduce the size. —*Industrial Gazette.*

How Bessemer Steel is Made.

We give the following concise description of the mode of making Bessemer steel from the query column of the *Manufacturer and Builder*:

A charge of pig iron—five or six tons—rich in silicon and low in phosphorus, is melted in a cupola furnace, and is allowed to flow into a heated vessel lined with a siliceous or basic lining. This is the converter, and the details of its construction are such that air may be blown up by a powerful blast through tuyers at the bottom, thus compelling these jets of air to pass through the molten metal. The converter is mounted on trunnions, so that it may be tilted over to receive the charge of molten metal; and when the metal is run in, the blast is turned on, after which the vessel is righted. The chemistry of the operation is about as follows: The heat of the charge is sufficiently great to produce chemical combination between the constituents of the iron and the oxygen of the air, which, when started, liberates heat enough to keep the charge at an intense heat. The oxygen of the entering air first combines with the silicon, after which the carbon begins to burn, and, according to the description of the late Mr. Holley, "the volume and brilliancy of the flame increase, and the surging mass grows hotter and boils over in splashes of fluid slag; the discharge from the mouth of the converter is a thick, white, roaring, dazzling blaze, and the massive vessel and its iron foundations tremble under the violent ebullition. Towards the close of the operation the flame becomes thinner, and when decarbonization is complete it suddenly contracts and loses illuminating power. The determination of this period is the critical point of the process.

"Ten seconds too much or too little blowing injures or spoils the product. At the proper instant, as determined best by the spectroscopic, or by colored glasses, but usually by the naked eye, the foreman turns down the vessel and shuts off the blast. The charge of melted 'spiegeleisen' is then run in, when another flaming reaction occurs. The vessel being still depressed, the steel runs into the ladle, pure,

white and shining, from under its coating of red-hot slag. A blanket of slag, most useful in preserving its temperature, follows it into the ladle. The metal is now led into the ingot molds. After the exterior of the steel has crystallized, the mold is removed, and the ingot is ready for reheating and rolling." The operation of conversion occupies about twenty minutes.

The burning out of the silicon and carbon in the operation is likewise attended with the oxidation of a portion of the iron, and to correct this, as well as to introduce the proper proportion of carbon, an iron rich in manganese, called "spiegeleisen," is added. This is introduced in a melted state after the blow, above described. If the steel is required to be low in carbon, less spiegeleisen is introduced than where a higher steel is wanted. The quantity of spiegeleisen added varies, therefore, from 5 to 10 per cent of the charge.

Delta Metal—An Important Discovery.

It has long been known that the introduction of iron into our alloys of copper and zinc materially alters the physical properties of the products for the better. Several attempts have been made to use iron in this connection, but hitherto without practical success. Experimentally the results have proved satisfactory, but when tried on a working scale the process has failed from a want of uniformity in the products. Among others who have directed their attention to the matter is Mr. Alexander Dick, of London, who, after careful experiment and research, has succeeded in introducing the iron into the alloy in such a way as to give good results on a practical scale. This success is obtained by previously alloying the iron in such a manner that it is combined in definite and known proportions with the zinc. When wrought iron is introduced into molten zinc the latter readily dissolves or absorbs the former. The exact point of saturation or the proportion dissolved or absorbed varies with the temperature at which the molten zinc is maintained during the process, and it is by carefully ascertaining and controlling this temperature that Mr. Dick has been able to succeed in obtaining a perfectly uniform product. The metal thus produced, and to which the name of Delta metal has been given, is stated to be as much superior to brass as phosphor-bronze is to gun metal, or as steel is to iron. It possesses great strength and toughness, and samples cast in sand give a breaking strain of twenty-two tons per square inch. Forged or rolled into bars it shows a tensile strength of more than thirty-three tons per square inch, and drawn into wire of 22 gauge it is found to stand sixty-two tons per square inch before breaking. It has an excellent color, is very easily worked, takes a high polish, and tarnishes less quickly than brass, and on the whole appears to be susceptible of a very wide application both for useful and ornamental purposes. —*London Times.*

Steel for Heavy Shafts.

An engineer at a meeting of the Society of Engineers at Aix-la-Chapelle gave some facts in regard to the qualities of mild steel for heavy forged work that tend to modify the growing confidence in that material as compared with iron. He said that a Bessemer steel shaft of a high speed engine belonging to a rolling mill broke suddenly while the engine was moving slowly. The shaft was replaced by one of iron. In an engine works on the Rhine a steel shaft of 15 3/4 inches diameter broke, and inside was found a hole large as a man's fist containing two steel balls that during the two years of the shaft's rotation had been worn quite smooth. Another engineer said that in casting steel ingots it is more frequent to have a porous casting in mild steel than in hard steel. If steel ingots have incomplete, hollow, or porous spots, these do not become welded together by further heating and working, but, after being rolled thin, they retain their porosity, as unwelded spots are retained in wrought iron. As these porous places are generally in the center of the ingot, the round bars, the piston rods, and axles made of it have also usually an internal weakness, which it is difficult to set right in the working, and which may cause breakages in the future. In the course of the discussion it was shown that steel that hardened on the surface or sudden cooling ought not to be deemed mild steel, and was treacherous in its character. No material capable of considerable hardening should be called iron, and, if narrowly examined, it will be seen that a great deal of the ingot iron specified as "incapable of considerable hardening" is, nevertheless, capable of very considerable hardening under certain circumstances, such as a sudden cooling of a heated shaft. This "inconsiderable hardening" is just sufficient to shrink the surface, produce tension, small cracks, and finally breakages.

BURNING SMOKE.—Aug. Hansen, a well-known practical engineer of long experience, says: "Attempting to burn smoke after it is once formed is useless, under a steam boiler. The temperature of the furnace must be increased, and a sufficient quantity of heated air admitted to prevent its formation. This, together with the plan of introducing small quantities of fuel at short intervals, and a well set boiler, is undoubtedly the best 'smoke preventer' of the present day.

SCIENTIFIC PROGRESS.

A Mistaken Philosophy of Growth.

Professor Lionel Beale, in a lecture before the Victoria Institute, London, thus alluded to mistakes in scientific data made by philosophers who rely upon assumptions: "Herbert Spencer, strange as it may seem, affirms that crystals grow, and that non-crystalline masses of various kinds grow. He declares that the accumulation of carbon on the wick of an unsnuffed candle is an example of growth. * * * There will be found some of the very remarkable inferences upon which his system of evolution in part rests, and which may be clearly proved to be erroneous. Indeed, not a few of the assertions he makes may be answered by a direct contradiction with advantage to the cause of truth. Non-living things do not grow, as he affirms, while all living things and every form of living material does grow, although he says, with respect to a living plant, that its increase is not growth. * * * The growth of the most minute particle of living matter is, as I have stated, a vital process, and is due to the operation of a force or power absolutely distinct from ordinary energy and from every form of force of non-living matter. Every kind of aggregation is absolutely distinct from growth, and does not involve the latter. Processes of aggregation may go on to all eternity without the occurrence of any change resembling or allied to that of growth. Growth, after all, is but one of several purely vital phenomena.

"It would be tedious were I to repeat the dictatorial utterances in argumentative form, which have been published far and wide for the purpose of leading people to believe that a living thing was like a watch or a steam-engine or a hydraulic apparatus. Moreover, some of the comparisons have been voluntarily abandoned by their authors in favor of others even more absurd. Such tricks as calling a watch a creature and a man a machine are hardly likely to mislead even the most ignorant after they have withdrawn themselves from the bewitching influence of the persuasive eloquence of the materialist prophet, and have commenced to calmly think over his extraordinary utterances, in order to extract any meaning that may be hidden by the frothy metaphors of modern physico-vital conjecture.

"This, the dullest, the narrowest, the most superficial of all creeds—materialism, which includes some mixture of atheism, and theism of various forms and hues—has been half accepted by hundreds of persons during the last few years. I believe all materialistic doctrines, vary as they may in detail, will be found to agree in accepting as a truth—if, indeed, they are not actually based on it—the monstrous assumption that the living and the non-living are one, and that every living thing is just as much a machine as a watch or a windmill or a hydraulic apparatus.

Professor Huxley has been continually propounding and putting forward conjectural utterances of the kind during the last twenty years, and it is surely now time that something more substantial should be brought forward in support of the dogmas than conjectural chains of causation. * * * Between purely vital and purely physical actions not the faintest analogy has been shown to exist. * * * Within a very few years the hypothesis of molecular machinery will probably be forgotten, and the operation of vital power, as distinct from any ordinary force of matter, will be generally admitted and taught. * * * Look at it how you may, you will not discover the smallest speck of firm ground of truth upon which to build any form of the materialistic doctrine.

Unconscious Bias in Walking.

Mr. G. H. Darwin, in *Nature*, states that some ten years ago he made a few experiments upon the subject of "Unconscious Bias in Walking." He began by walking himself, and getting various friends to walk, with eyes shut, in a grass field. All walked with amazing crookedness in paths which were not far removed from circles. Two of the circles described were not more than fifty yards in diameter, although the pedestrians thought they were going straight. All diverged to the right, excepting one, who was strongly left-handed. "I then got eight village school-boys, from ten to twelve years of age," continues Mr. Darwin, "and offered a shilling to the boy who should walk straightest blindfold. Before the contest, however, I dusted some sawdust on the ground, and after making each of the boys walk over it, measured their strides from right to left, and left to right. They were also made to note, and the foot on which they hopped was noted; they were then made to jump over a stick, and the foot from which they sprang was entered; lastly, they were instructed to throw a stone, and the hand with which they threw was noted. Each of these tests was applied twice over.

"I think they were all right-handed in throwing a stone, but I believe that two of them exhibited some mark of being partly left-handed. The six who are totally right-handed strode longer from left to right than from right to left, hopped on the left leg and rose in jumping from that leg. One boy pursued the opposite course and the last walked irregularly, but with no average difference between his strides. When I took them into

the field I made the boys successively take a good look at a stick at about forty yards distance, and then blindfolded them and started them to walk, guiding them straight for the first three or four paces. The result was that the left-legged boys all diverged to the right, the right-legged boys diverged to the left, and the one who would not reveal himself won the prize. The trial was repeated a second time with closely similar results, although the prize winner did not walk nearly so straight on a second trial.

"I also measured the strides of myself and of some of my friends, and found the same connection between divergence and comparative length of stride. My own step from left to right is about a quarter of an inch longer than from right to left, and I am strongly right-handed."

Mr. Darwin believes that nine out of ten strongly right-handed persons are left-legged, the reason being that every active effort with the right hand is almost necessarily accompanied by an effort with the left leg, and a right handed man is almost compelled to use his left leg more than the other.

The History of Thermometers.

At the meeting of the Royal Meteorological Society, held on March 19th, the president, Mr. R. H. Scott, F. R. S., read a paper entitled "Brief Notes on the History of Thermometers." The name of the actual inventor of the instrument is unknown. The earliest mention of it, as an instrument then fifty years old, was in a work by Dr. R. Flood, published in 1638. Bacon, who died in 1636, also mentions it. The earliest thermometers were really sympizcometers, as the end of the tube was open and plunged into water, which rose or fell in the tube as the air in the bulb was expanded or contracted. Such instruments were, of course, effected by pressure as well as temperature, as Pascal soon discovered. However, simultaneously with such instruments, thermometers with closed tubes had been made at Florence, and some of these old instruments were shown at the loan collection of scientific apparatus at South Kensington in 1876. They are in the collection of the Florentine Academy, and in general principle of construction they are identical with modern thermometers.

Passing on to the instrument as we now have it, Mr. Scott said that most of the improvements in construction in the earliest days of the instrument were due to Englishmen. Robert Hooke suggested the use of the freezing point, Halley the use of the boiling point and the employment of mercury instead of spirit, and Newton was the first to mention blood-heat. Fahrenheit was a German by birth, but was a protégé of James I., and died in England. Reaumur's thermometer in its final form owes its origin to De Luc; while the centigrade thermometer, almost universally attributed to Celsius, was really invented by Linnaeus. Celsius' instrument had its scale the reverse way, the boiling point being 0° and the freezing point 100°. Mr. Scott then gave a brief account of some of the principal forms of self-registering and self-recording thermometers.

COMBUSTION PRODUCTS OF VARIOUS ARTIFICIAL LIGHTS.—*Zeitschrift of the Electrical Exhibition in Vienna* furnishes the following data respecting the character and quantity of the combustion products yielded by various forms of artificial light, the values being reduced to 100 candles and one hour duration of light.

	Water vapor.	Carbonic acid.	Heat in Kilograms.	Cub. meters.	calories
Electric arc light	0.00	0.00	57		
Incandescent light	0.09	0.00	230		
Argand gas lamp	0.85	0.45	480		
Petroleum lamp	0.60	0.35	730		
Paraffin candle	0.99	1.22	920		
Tallow candle	1.05	1.45	970		

From these figures it will be perceived that the tallow candle, for a given amount of light vitiates the atmosphere to a greater degree, and gives out a greater amount of heat, than any of the others. The paraffin candle is next in order. Then follows the petroleum lamp; then the argand gas lamp. The electric lights both of the arc and incandescent type, show their great superiority in quality over their would-be rivals by the total absence of objectionable combustion products, and a very low heat emission.

LIQUEFIED CARBONIC ACID AS A MOTIVE POWER.—We learn from one of our German exchanges that the steam fire engines of Berlin are provided with pipes for the discharge of compressed carbonic acid into the steam cylinder. When the engine starts from the station the boiler is heated, and on arriving at the fire the carbonic acid is first employed as a motive power, then the gas and steam together, and finally, when the proper steam pressure has been obtained, the steam alone. By this method of utilizing the compressed gas, the fire engine is brought into service four or five minutes earlier than would be possible with steam alone. The amount of carbonic acid gas used each time is about 17½ pounds.

A VAST NUMBER OF SPECIES.—There are supposed to be about 1,000,000 species in the animal kingdom. Of beetles alone over 100,000 species are known, and the whole number of insects is set at 500,000. Of the higher animals there are 1,200 mammals, 7,500 birds, 2,000 reptiles and 10,000 fishes.

SAN FRANCISCO:

Saturday Morning, May 10, 1884.

TABLE OF CONTENTS.

EDITORIALS.—Standard Time; New Miners' Pick, 317. Passing Events; Copper; Industrial Notes; Miners' Wages at Tombstone; Powder; The Technical Society, 320. The Manufacturers' Association; Mining Machinery; Prospects; On Rock Drills—No. 3, 321.

ILLUSTRATIONS.—Diagram Showing the Actual and Estimated Progress in the Arlberg Tunnel, 317. Map Showing the Different Divisions of Standard Time, 321.

CORRESPONDENCE.—The New Copper Assay; The Content of Mucic, 318.

MECHANICAL PROGRESS.—Wire Rope and its Management; How Bessemer Steel is Made; Delta Metal—An Important Discovery; Steel for Heavy Shafts; Burning Smoke, 319.

SCIENTIFIC PROGRESS.—A Mistaken Philosophy of Growth; Unconscious Bias in Walki et. The History of Thermometers; Combustion Products of Various Artificial Lights; Liquefied Carbonic Acid as a Motive Power; A Vast Number of Species, 319.

USEFUL INFORMATION.—Making and Applying Kalsomine; Painting is no Expense; Invisible Patches for Footwear; A New Feature in Printing Art, 323.

GOOD HEALTH.—The Philosophy of Coughing; Are Coal Tar Colors Poisonous; The Cure of Saccharine Diarrhea; Simple Cure for Cold Feet; The Size of Drops, 323.

MISCELLANEOUS.—Metallurgy of Nickel; Cœur d'Alene Mining Laws, 318. How to Run a Mill, 323.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 324-25.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 328.

Business Announcements

Millmen Wanted—Theo. L. Chase, Hassayampa, A. T.; Steel Shoes and Dies—A. Doble, S. F.

See Advertising Columns.

Passing Events.

Probably the most prominent piece of news from the mines is that which announces the closing down of several Tombstone, Arizona, mines, on account of the miners' wages question. We refer more fully to the subject in another column.

From the same Territory comes the unwelcome news that some of the copper mines there must close down—one already having done so—until the price of copper is more satisfactory, as they can make no profits at present rates.

If we believe all the reports from the Cœur d'Alene region, a number of new districts or gulches have been found and rich developments made. The people up there seem to be in rather an excited state just now, however. It is to be hoped that half of the reports are true, since if they are, a remarkably rich mining country will be developed this summer.

THE PARADISE MINES.—J. P. Courter, who has had extensive experience in mines, returned yesterday from a visit to Paradise. He was very favorably impressed with the appearance of the mines, and it is probable that an Eastern company with which he is connected may remove a fifteen-stamp mill from Lewis to Paradise.

The managers of the National Mining and Industrial Exposition, say that owing to the apathy of the citizens of Denver, in the matter of popularizing said institution, there will be no exhibition held this year in Denver.

The number of bills introduced in the House of Representatives during the present session of Congress is 6,538, not one-sixth of which will become laws.

Copper.

In the last number of the PRESS was an article on the cost of mining copper. The subject is one of the greatest interest on this coast, where our mines, laboring under disadvantage of high rates of transportation, and distance from commercial centers, must compete with the enormously productive and rich mines of the Lake Superior region. The Arizona mines, rich as are their ores, and easy as most of it is to work, will have to economize greatly to make any profits at present price when transportation is paid. Indeed Governor Tittle of Arizona, expresses the opinion that unless there is a revival in the price of copper, the working of such mines in that territory as yield copper only and whose ores are of low grade, will be seriously interfered with. The Calumet & Hecla, of the Lake Superior region, largely control the market. As their product is absolutely pure and especially malleable, they usually receive about \$20 per ton, or one cent per pound, more than any other copper mines. As they are now selling their copper at thirteen cents per pound, other producers will only obtain about twelve cents per pound, and at that rate very little, if any, margin is left for the class of producers in Arizona, referred to.

There is an immense copper belt in Arizona, but an increase of railroad facilities are needed to develop it. In Northern Arizona the leading copper camp is in the Black Hills where the United Verde Copper Company are working an ore, the gold and silver in which enables them to continue operations regardless of what they get for their copper. They have just built a 47 mile road which has cost \$10,000. The teams haul in about 350 tons of coke a month and 35 tons of bullion out. The freighting costs about \$15 per ton. All the copper mines in the territory labor under the burden of having to pay higher freights to send their products to market, than is the case with the Eastern mines. The distances are great. Much of the Arizona ore is smelted with the greatest ease, and the water-jacket furnaces in universal use do their work in a most satisfactory manner. Still the very low price of copper is reducing profit to a very small margin indeed.

Since writing the above we find the following paragraph in the Tombstone (Arizona) *Epitaph*: M. H. Smith writes us from Johnson, that on April 30th, the superintendent of the Peahody mine notified the men that he had received orders from headquarters to close the mine and pay all the men off. The smelter will continue to run until the ore on the dump is exhausted, when they too will shut down. The reason assigned for this action is the rise in the price of coke and the fall in that of copper.

Industrial Notes.

The Risdon Iron Works are building an addition to their shop room in the shape of a new boiler shop. The building will be 275 feet long, reaching through the whole block. It will be 45 feet wide and two stories high.

Our local woolen mills—the Golden Gate and Pioneer—are working on goods for Eastern orders largely.

Work has begun upon the shops of the California and Nevada Railroad at Emery station, in Alameda county. A large force of men was set to work on April 28th.

The iron and steel works at Los Angeles are busy preparing their shops with new machinery. They will use one of the Ohmew engines, made in this city. The tools are all of the latest pattern.

The cigar makers are gradually getting rid of Chinese help and putting white men at work. Half the working force of one of the largest factories here is now white.

The new paper mill at Compton, Los Angeles county, is rapidly approaching completion.

The journeymen painters of this city and Oakland are on strike for higher wages. In this city there are some 80 or 90 shops, employing about a thousand journeymen painters, at wages rating from \$4 a day to choice men to \$2 50 a day to others, averaging about \$3 per day all around. The Master Painters' Association wants to pay 33 cents per hour. The Journeymen Painters' Association ask for \$3 50 per day and nine hours work instead of ten. Their demand not being acceded to, the strike was made, something like 500 men walking out of 16 or 18 shops.

Miners' Wages at Tombstone.

A very serious aspect of affairs exists at Tombstone, the principal mining district of Arizona. The men in some of the prominent mines were notified that wages would be reduced 25 per cent on May 1st. This would bring wages down to \$3 per day from \$4, the amount paid since the camp started. This the men have refused to accede to and several mines have shut down with more to follow. A miner's union has been formed, the men have paraded with brass bands and are determined to have \$4 per day. The superintendents say they must either work for \$3 per day or the mines will be kept shut down. The grade of ore in the mines has gradually fallen off until some of the mines have been losing money. The reason of the closing of the Grand Central mine is thus given by Superintendent Gage:

It closed simply because its owners determined that it was suicidal to run it at a loss. For the past four months the company has been steadily losing money. Mr. Gage, taking a volume containing the receipts and expenditures of the mine for the past year, showed the reporter that during the month of January the loss was about \$2,000. For February about a stand off. For March over \$7,000 with an approximated loss for April of \$25,000. A table of battery assays showed that the ore now coming from the mine and being shipped to the mills, averaged less than \$20 per ton.

This ore is on the one hundred and two hundred feet levels, in which we quit working long since for the reason that it was so low grade. The ore worked for the past two years has come from below the two hundred level. This being exhausted we went back above, thinking the grade might improve as the work was prosecuted, but you have seen the result.

With a mill at the mine, and the consequent saving, it might be made to pay at the present rate of wages. Not only this but some of the ore is very refractory. With present facilities we have not been able to save more than from 70 to 80 per cent. I have shipped several samples however to the Ontario mine and had it worked up to 94 per cent, which is you see, quite an item. The probabilities are that we will get the Ontario processes and begin again, but while we are getting new machinery, etc., you can hardly expect us to run the mine at a loss. It takes time to make changes such as are contemplated. The Contention mine will shut down soon.

Powder.

Such has been the competition among the powder manufacturers of this coast that for some time no profits have been made, and, in fact, some have been working at a dead loss. Some of the smaller companies first succumbed. Then a large company, the Tonite, had to stop manufacturing. The Safety-Nitro, on the strength of a big railroad contract, had quite a boom, but that is some time over, and the company has not made much of a stir of late. The Giant, Vulcan and California powders, and some others, have been sold for many months at such low prices that the manufacturers have made no profits.

It is thought now that before long the local powder companies will come to some sort of agreement, so that they can make a little profit on their goods. In which case, of course, miners must expect to pay a little more for their powder than they are now doing.

THE hoisting works of the Imperial quartz mine, situated on the north side of Deer Creek, two and a half miles north of Grass Valley, were destroyed by fire on Sunday night, the conflagration commencing at about 11 o'clock, and was caused by the explosion of 25 or 30 pounds of giant powder. At the time of the fire none of the employees were about the works, as no work was done about the mine on Sundays, further than to work the pump for a portion of the day. The supposition is that the powder was fired by some malicious person. The loss is \$2,000.

PEOPLE may now go faster from one distant point to another over the water than over the land. The New York *Sun* says: "If there were a straight stretch of water from New York to San Francisco, there is no train on the present schedule between the two points which the Oregon would not leave behind her."

SAMUEL C. STERENS one of the foremen of the Ontario mine Utah, was killed by falling from the cage in the shaft last Monday.

The Technical Society.

The first general meeting of the Technical Society of the Pacific Coast since the completion of the organization, was held on Friday of last week in the society's new rooms, 413 Sutter St., Col. Geo. H. Mendell in the chair. The resignation of Wm. Ham. Hall from the Board of Directors, on account of non-residence was received. Mr. George W. Dickie of the Union Iron Works was unanimously elected to the vacancy on the Board, thus giving the mechanical engineers proper representation in the governing body of the society.

Wm. Hammond Hall, State Engineer, read a paper "On the Sewage Question in California."

The writer considered the various classes of sewage and their disposition, and defined the word and the kinds of refuse implied in its use. The "sewage question" applies to the problem of final disposal of sewage matter and sewage. The term "sewage matter" applies to all refuse substances which are, or may become noxious in establishments under human control. The term "sewage" applies to waste matters, and liquids from such establishments with their burden of sewage matters. The term "final disposal" contemplates the disposition of sewage and matter in an unobjectionable way to its locality or public. The dry wastes of cities and towns was considered, such as yard scrapings, etc., and methods of disposition of garbage and rubbish described. The writer cited examples of the disposal of refuse in large cities, mentioning New Orleans, New York, Leeds and Glasgow.

Then came consideration of sewage matter proper—that is, the more noxious forms. The cesspool system was described and condemned emphatically. The dry systems were described and methods enumerated. Of the "water carriage" system Mr. Hall had much to say, taking up the branches of pollution of waters, of rivers, water-courses, etc. The question of land being the proper purifier of liquid sewage was discussed and also the action of the soil and air in effecting the disposal of sewage. Then came up the causes of opposition to irrigation, intermittent downward filtration, the reform movement, facts that were overlooked, value of sewage in England, the sludge complication, etc. Examples of sewage irrigation were cited and results described as experienced in London, Edinburgh, Paris, Dantzic, Berlin and various points in the United States. Filtration, precipitation and purification were considered under separate heads. Methods of sewage treatment were described in detail, such as the Coventry process, the native guano, or A. B. C. process, phosphatic process, lime process.

The conclusions drawn from experiences elsewhere were applied by Mr. Hall to the circumstances existing in California, where our climatic conditions are very different from most locations where the problems of sewage disposal have been or are being solved. Mr. Hall's local application of the conclusions were of great interest. The paper will soon be published by the society. A meeting will shortly be held when it will be discussed.

Academy of Sciences.

The regular semi-monthly meeting of the California Academy was held on Monday evening, Professor Davidson in the chair. D. H. Behr read a paper on "The Germ Theory of Disease," which occasioned some discussion. Edward Probert was elected a resident member. Professor Davidson described his 20-day trip over the recently completed railways of Mexico. Having passed the arid Colorado desert, he reached El Paso, at an elevation of 4,000 feet above the sea, and encountered great tablelands, where the annual rainfall is three to four inches and cloud-bursts are frequent. The valleys are simple rock-gorges. The region is middle ground between the northern and southern systems of winds and weather. For 400 miles south of El Paso no signs of life appear. This aridity reaches to Chihuahua, where the rainy season is from May to September. At 7,600 feet mining is visible on every side and the utmost activity prevails; thence descending into a valley 6,000 feet high, wider than that of the Sacramento. Agriculture is carried on by the old methods of oxen drawing plows of crooked sticks, but wheat and corn grow abundantly. Plowmen receive \$5 a month to work from 5 A. M. to 7 P. M., less one hour nooning.

He described the trip to Pueblo and the city of Orizaba over the central plateau, and the descent of 8,500 feet, to the Atlantic towards Vera Cruz, where British engineers have constructed the railroad with a grade of 212 feet a mile, requiring a 75-ton engine to draw 16 cars at 8 miles an hour. Eighteen cents a day supports these people, who have been completely secluded from the world. All small land owners appear thrifty; but large estates are neglected.

The Manufacturers' Association.

The Directors of the Manufacturers' Association held their regular meeting at their office, 43 Merchants Exchange on Monday. President Hallidie was in the chair, and Directors Spaulding, Garratt, Phelps, Harazthy, Kerr, Hecht and Harney, and George C. Hickox, Secretary, were present. The Secretary reported that since the last meeting the association had sent a memorial to David Mc'hure, State Senator, urging him to use his influence in order to secure an amendment to the Constitution permitting the exemption of all tools and machinery used in manufacturing, and all raw material used for manufacturing. Also a communication requesting all School Trustees and Boards of Education in the State to examine into the merits of text-books that may be prepared and published on this coast, and all things being equal, to give them the preference.

The 3,000 copies of the association's circular, explaining its purpose and organization, had

Mining Machinery.

There is no economy in buying any kind of machinery because it is cheap. In the case of mining machinery cheap appliances may be the cause of great loss in more ways than one. Without counting the expense of repair and replacement, the delays incident to breakage are very expensive. In pumping gear thousands of dollars of damage may be done in a short time and much time be lost if it breaks. With the hoisting gear there is danger to human life and property. A mill that is a rattle-trap is a constant source of expense and dissatisfaction, and engines that require frequent overhauling and repairs are an annoyance and a source of expenditure. Cheap machinery of this kind never pays. In saving in the original cost there is often loss in the long run.

It is always well to select as good machinery of the class as possible. It is cheaper in the end. People who spend a week or two running around to get lowest bids and cramp the bidder

Prospects.

Holes in the ground, even if deep, are not mines. Too many people, however, are apt to think so. No one holds the opinion either more firmly than the very man who ought to know better—the prospector. He cherishes the belief that signs of a ledge and a moderate sized hole more or less deep, with a little dump alongside the windlass, is a mine. The prospector believed this so firmly to be a mine for so long a time that he convinced many others that he was right. Thousands of these holes have been bought before this, with the understanding that they were mines. And corresponding thousands have found out their mistake. To have a mine it is necessary to have a hole vertical, horizontal or inclined; but having a hole, it does not follow that one has a mine at the bottom or end of it. People have pretty well found this out. They do not go around bonding or buying these holes. To attract attention now and have any sort of a

On Rock Drills—No. 3.

[Written for the Press by Geo. J. Speight, C. E., 418 California St., San Francisco.]

This different character of the ground must be taken into consideration in comparing the results in the two headers. For detailed data about the work, the reader is referred to the annexed tables. The diagram given shows the actual progress made in each header compared with the assumed progress of 10.82 feet per 24 hours, serving as base of the contract. It also gives the average daily progress per 24 hours.

The progress of the heading made within a certain length of time is not well adapted to form a fair base for an impartial comparison between various systems of drilling machines, as it depends too much upon the nature of the rock, which is different in nearly every case.

Tables on next page go still more into the details of drilling, and cover the period from Sept.,

DIAGRAM SHOWING THE ACTUAL AND ESTIMATED PROGRESS IN THE ARLBERG TUNNEL.

been distributed among all the manufacturing firms of the State, and all persons interested directly or indirectly, with the manufacturing interests. The newspapers had also been sent copies, and many of them had given friendly notices of the association, commending its purpose as worthy of public approval.

The committee appointed to examine into the abuse of the license tax by druggists from other States had had several conferences with similar committees from another body, and stated that the authorities were exercising vigilance and enforcing the ordinances. A few convictions had been obtained, and if the ordinances at present in force are carried out, they thought they would remedy the evil.

The Association is actively at work carrying out the object for which it was organized, and is by no means a more passive society, but one which proposes to do as much for local manufacturers as possible. The officers are practical and energetic men.

The probabilities that a general strike of iron-workers in the West will be inaugurated June 1st are increasing. Oliver Bros. & Phelps' three mills at Pittsburg suspended operations, and it is said will not resume until the wages question is settled. This action is taken as an indication that the manufacturers are determined to make a reduction. The workmen show no signs of yielding.

down to the lowest notch never get satisfactory work. Good articles are worth a fair price. Every hundred dollars off the fair price lessens the value of the article in some way. Foundrymen do not run their works for glory. They want to make money as others do. They take a pride in their work generally, and like to do a good job for a customer. People, however, who run around looking for cheap things are not given the best things. They get what they are looking for. There is no better mining machinery made in the world than in San Francisco. The foundrymen whose names are in our advertising columns have been for many years in the business, and have the necessary experience to make machinery of any kind in first-class style. There is no excuse, therefore, for people to buy any "rattle-trap" mills or machinery that will be constantly breaking down.

GEORGE M. SMITH of Gold Hill has returned home from a six weeks' absence in Butte City, Montana. He says there are 8,000 or 9,000 people in Butte, about 2,000 men at work, 1,000 men who want work and can't find it, and another 1,000 who look for work, but do not wish to find it. The mines are looking well, and the country on the whole prosperous. Miners receive \$3.50 per day. It is said that owing to the fact that at Butte, Montana, they have found it expedient in some of the larger mines to send for Constock miners, against the latter class there has engendered a very strong prejudice.

market value, there must be a fair show of ore that will pay to ship or work, and pay a profit. Then the buyer will see about buying. Prospectors who recognize the signs of the times now give up trying to bold thirty or forty claims in a district, and concentrate their force on one. They dig and delve until they have something to show. When developments warrant, they can sell. It will be said this is hard on a man with no money. So it is, perhaps; but men without money in other branches of business have it hard too, until they build up something worth having. The hardship is imaginary, not real. Capital seeking profitable investment must take many chances anyway. It is not too much to ask the prospector to show that he has a mine before asking capital to develop it.

W. H. CLARK, who shot himself at Virginia last week was one among the first settlers of the Constock. In early days he was the foreman in the Chollar mine. Subsequently he went to Pioche, where he was superintendent of several mining properties. He has been engaged in the brokerage business in Virginia for ten years past. He has always been very careful in all business matters. When there has been any development on the lode he has always been found among the first to go underground and personally examine the "find." He was an excellent judge of ore, and of the value of quartz or other developments thought to be favorable.

1882, to Sept., 1883, during which the whole work was in its height of activity, and which can be considered the maximum capacity. The diagram shows graphically the progress actually made in comparison to the progress accepted as a base for the contract. The contractor was 13 months ahead of the time stipulated, for which he received a premium of \$324 for each day. It will be of interest to insert here the main points of the contract.

The main points of the contract of the Airlberg tunnel are as follows:

From the 1st day of February, 1881, the daily progress of the bottom header on the east side has to be at least 10.8 feet. The completed portion of the tunnel must at no time be more than 180 days behind the face of the bottom header, so that the entire tunnel, including the gravelling of the road bed, will be completed at the 180th day after the meeting of the two headers. (It was estimated that this would take place in the middle of the tunnel, and the tunnel would be opened for traffic about the middle of August, 1885.)

For each day the tunnel is finished after that date the contractor has to pay a penalty of \$324, while for every day the tunnel is finished sooner he will receive a premium of the same amount.

These penalties or premiums will be actually accounted for at each monthly settlement.

The progress in all the other sections of the work in the tunnel must also be at least 10.82 feet per day. The face of the top header must never be more than 328 feet behind that of the bottom header, and the total length of the un-

finished tunnel, simultaneously under construction, shall never be more than 1,965 feet.

The gravelled and finished road-bed of the first kilometer (0.62 miles) on either side must be turned over to the Government engineers 30 days before either half of the tunnel is completed. The remainder has to be so turned over that 40 days after the day of the acceptance of the first kilometer, the track can be finished in the whole tunnel.

If at any time any one of the sections of the work in the tunnel should be more than 1,000 feet behind the programme, the contract ceases

mechanical department, the contractor is responsible for its success. The contractor is obliged to have a previous understanding with the Government about the additions and alterations to be made to the installation. He has to make estimates and specifications thereof, to solicit bids from manufacturers, etc. The Imperial Department then makes from time to time an agreement with him, taking his estimates and specifications as a base. Such additional work has to be done by the contractor, paid for by the Government; after it is finished the Imperial Department inspects the same, accepts it and turns it over to the contractor for his use, free of charge, until the tunnel is finished. The finished sections of the tunnel are to be examined, and the accounts for them settled in the first week of January of each year.

The contractor guarantees his work for two years. The securities deposited by the contractor, \$243,000, will be returned gradually in installments, but only to such aggregate amount that never less than \$121,500 shall remain in the hands of the government. The entire installation—all the necessary machinery, buildings, pipe-lines, etc., etc.—whether they are procured with or without assistance from the contractor—remain the property of the government, and are only loaned to the contractor for use during the construction of the tunnel free of charge.

It was agreed that the first installations should be completed at the expense of the government until the additional amount so expended would have reached the sum of \$194,250 for the east header and \$202,500 for the west side. (When the contractor commenced work the aggregate amount expended by the government for the installations was \$255,000.) Any savings on the above amounts belong to the government, in addition to its rights as proprietor of the entire installation. The contractor has to provide, at his own expense, all the tools, tracks and switches, boarding houses, all draft animals and the necessary stables for the same, all arrangements for storing dynamite, etc.

The following prices were made the base for the contract:

The price of one running meter of tunnel in the first kilometer from each month is taken as the base; for each following kilometer a certain price is added to the one of the proceeding kilometer. The prices are:

1. Bottom header, first kilometer \$75 per meter (\$22 90 per foot.)

Additional price for each following kilometer, \$5 per meter (\$1 53 per foot.)

2. Top header, first kilometer, \$50 per meter (\$15 25 per foot.)

Additional price for each following kilometer, \$2 50 per meter (\$0 76 per foot.)

3. All the other work, as enlargement, masonry, arching, etc., but excluding masonry of sub-drain, is classified according to the kind and thickness of the masonry, etc., into ten different types, with different prices, of which the following are the most important ones:

Type No. 1.—No masonry or arching, but sufficiently large excavation to give room for a masonry lining 1.64 ft. thick, first kilometer, \$200 per running meter, (\$61.10 per ft.) Additional price for each following kilometer, \$10 per meter, (\$3.02 per ft.)

Type No. 2.—With arch and abutments in range rubble masonry, 1.64 ft. thick, no invert, first kilometer, \$295 per running meter, (\$90 per ft.) Additional price for each following kilometer, \$15 per running meter, (\$4.50 per ft.)

Type No. 6.—With arch 2.78 ft. thick and abutments 3.6 ft. thick and invert 2.13 ft. thick in range rubble masonry, first kilometer, \$545 per running meter, (\$166 per ft.) Additional price for each following kilometer, \$25 per running meter, (\$7.62 per ft.)

Type No. 10.—With arch 2.95 ft. thick, abutment 4.1 ft. thick and invert 2.62 ft. thick in cut stone masonry, first kilometer, \$815 per running meter, (\$248 50 per ft.) Additional price for each following kilometer, \$35 per running meter, (\$10.68 per ft.)

Prices for the sub drain, 2.62 ft. high in clear and with clear widths varying from 1.97 ft. to 2.62 ft., to 3.28 ft. are respectively \$2.44, \$3.03 and \$3.65 per one running ft. In the first kilometer, with additional prices of \$0.15 per running ft. in each following kilometer.

The estimates were as follows:

For the east half.....\$2,413,842
For the west half.....2,441,503
Messrs. Lapp & Ceconi were the successful bidders with 5 per cent addition to the estimate on the east half and 2 per cent to the west half, making the final cost as follows:

East half.....\$2,534,532
West half.....2,490,333
Total.....\$5,024,865

According to the final estimate the total cost

of the tunnel, including the graveling of the road-bed, will be \$6,777,750, or \$201 per running ft.; this depends largely, however, upon the amount and kind of masonry yet to be done.

Cost of installation up to Dec. 31, 1881, at which time the same can be considered as nearly completed:

East Side, St. Anton.	
1. Grading and roads.....	\$8,003 07
2. Water-power (wheels, pipes, flumes, etc.).....	57,904 13
3. Machines: 2 turbines, 4 compressors, temporary ventilation consisting of a locomotive and fans, the first installment of drills consisting of 14 drilling machines, 2 carriages, 400 drills, etc., 6 water-pressure engines, 6 compressors, 1 air reservoir, 4 water-pressure engines, 4 blowers, all the necessary pipes and accessories.....	161,499 49
4. Buildings.....	74,640 26
Total.....	\$302,046 95

West side, at Langen.	
1. Grading and roads.....	\$14,131 64
2. Water-power (wheels, pipes, flumes, etc.).....	85,306 62
3. Machines: 1 turbine, 4 pumps, 2 accumulators, temporary ventilation, first installment of drills consisting of 3 carriages, 3 hydraulic drills, with the necessary drills, rods and 300 drill bits and all accessories, 3 turbines, 8 pumps, 2 accumulators, steam engine of 30 horse-power as reserve, with 22 boilers, definite ventilation consisting of 1 turbine, 2 sets of ventilators, all the necessary pipes and accessories.....	120,996 12
4. Buildings.....	78,308 47
Total.....	\$298,833 05
Total for both sides together.....	\$500,880 00

The meeting of the two advance headers of the Arlberg tunnel is a most interesting and important event. The unprecedented rapid progress, which was 2.6 times as great as that in the Mont Cenis, and nearly double that in the St. Gothard tunnel, and the proper following of the enlargements and the arching, decide

bottom header. It may be mentioned here, that M. Bridel, the Chief Engineer of the Gotthard Railroad, as well as his immediate predecessor, the now deceased W. Hellweg, pronounced both in favor of the bottom header.

The connecting drill-hole was bored on the third anniversary of the beginning of machine-drilling. Therefore, the progress made in three years was 32,242.4 feet; or per day, an average of 29.52 feet, which has never been done before, anywhere. The survey showed a deviation of the center line of .65 feet, which, however, was determined immediately after the connection, only by plumb-lines without any instruments. The level was absolutely correct, while the length was between 19 and 20 feet shorter than the one determined by triangulation. This is a rather interesting fact, as the same difference had been observed at the Mont Cenis and St. Gothard tunnels.

The following table shows the state of the different divisions of the tunnel on the day of connection:

TABLE SHOWING THE WORK DONE AND YET TO BE DONE ON NOVEMBER 14, 1883.				
	East Side.	West Side.	Together, 33,650.9 ft.	Header driven from east portal 2,414 ft. more than from west portal; therefore, point of connection 1,207 ft. west of middle of tunnel. Difference in total length, 23 ft. Together, 31,438 ft. Remains to be finished, 2,136 ft. Total length of top header, 33,595 ft.
Bottom header finished.....	18,032.5 ft.	15,618.4 ft.

Experience at Sonnstun Tunnel.

Experience with the Brandt drill at the Sonnstun tunnel in Austria. The Sonnstun tunnel is 4,690 feet long. The contract to finish the same called for a very short time, therefore two lateral drifts were run from the mountain side, so furnishing four additional working faces. It was commenced entirely by hand labor. But after 2,630 feet were finished, it became apparent that the tunnel could not be completed in time. The rock encountered was an exceedingly hard and close dolomite and limestone. The contractor, therefore, concluded to put on a Brandt hydraulic drill. This was in January, 1877; April 11, same year, the machine drilling commenced. The motor in this case was a steam engine 9x9 inches, with two boilers capable of furnishing 20 or 30 horse power.

The drill column had a weight, when filled with water, of 308 lbs. The diameter of its piston was 6 in. and of the piston-rod 5 1/2 in. The drilling-machine itself weighed 264 lbs. The diameter of the piston was 4 1/2 in. and that of the piston-rod 4 in. With a pressure of 1100 lbs. per square inch, the forward pressure forcing the drill against and into the rock, was equal to 13,400 lbs. The drill-bit had an exterior diameter of 3.15 in. and had five teeth, each 7-16 in. wide. The above pressure was distributed upon these five teeth, each of which exercised a total pressure of 2,680 lbs. or 393 lbs. for each one-sixteenth of an inch of its width.

The two hydraulic motors turning the drill, used about 530 gallons of water per one hour drilling. Only one drill was used in the face of the heading. On an average it made 1 1/2 in. drill-hole 3 1/2 in. wide per minute in hard, uniformly solid limestone. The face of the header had an area of 70 square feet and required only from three to five drill-holes, each about 4 ft. 3 in. deep. It took on an average three hours to drill these holes. The average progress of the drift per 24 hours was 6.7, and per one attack 1.87 ft. One running foot of heading required from 13 to 17 lbs. of dynamite. The average time required for one attack was 5 hours and 45 minutes, of which the drilling took 2 hours and 45 minutes. The wearing off of the drill-bit was slight. The 944 ft. of drift made by these machines at the Sonnstun tunnel required not more than 80 drill-bits altogether, none of them, after four months use, were so much ground off that they could not be used again. The repairs of the machines proper were practically none, as the driving of the 2,225 ft. of drift including enlargements did not require any other repair than the replacing of a few packings in the moving parts.

The making of a hole three and one-eighth inches in diameter and four feet three inches deep required on an average thirty minutes, i. e., from the beginning of the actual drilling to the completion, in which the drill bit had to be renewed from three to four times. The pressure can be so well regulated that the different hardness of the rock does not affect it at all, as it does in a percussion drill, where the sudden meeting of a soft seam only too often breaks the machine. For experimental purposes the drill was worked through cavities in the rock without the slightest damage to the machine or interruption of the operation.

The drill bits were never heated, as the water

and the tunnel will at once be constructed at the expense and risk of the contractor, by the Imperial Department of Railways.

The contractor is responsible for the consequences of ordinary and extraordinary accidents. Only in case of war or epidemic he is entitled, under certain conditions, to extra compensations, the amount of which, considering only the actual additional expenses accrued to the contractor, is fixed alone by the Government.

Although the Imperial Department of Railways reserves for itself a leading influence upon the system of working the tunnel, and upon the

playing around them cools them and cleans the hole very effectively. From two to three men were needed to run one drill.

The total cost of the entire installation, including everything, was as follows,

1 Grading.....	\$872 00
2 Machine department, boilers, feed pumps, engines, pumps, accumulator, centrifugal pump, ventilator, lathe, and complete set of tools, also labor of setting up.....	5,625 00
3 Four hydraulic drills, complete with all accessories.....	4,800 00
4 Pipes.....	2,775 00
5 Freight, duty, salaries and miscellaneous.....	1,600 00
Total.....	\$15,672 00

The cost of one running foot of heading, including proportion of first cost (but allowing a sum of \$5,875 to be deducted from this first cost realized by the sale of the machinery) was as follows:

1 Proportion of first cost.....	\$10 39
2 Cost of machine drilling and ventilation.....	9 62
3 Other work in heading (blasting, removing debris, timbering, etc.).....	12 90
Total.....	\$32 91

or one cubic yard of excavation cost about \$12 70. This was the first railway tunnel in which the Brandt drill was practically tested—with the exception of a few experiments made previously in the Pfaffensprung tunnel of the Gnthard railroad.

Pfaffensprung Tunnel.

The cost of the entire installation for the Brandt drills and extra part was \$8,000.

Average time occupied by drilling to make one meter of heading.....	4 h. 12 m.
Average time occupied by blasting, removing dirt, etc.....	5 h. 24 m.
Number of drill holes for one meter of heading made.....	6 6
Total length of drill holes for one meter of heading made.....	21 6 ft.
Number of drills sharpened for one meter of heading made.....	26 4
Pounds of dynamite used for one meter of heading made.....	41 5

The cost of one meter of heading was as follows:

Proportional cost of installation.....	\$8 00
Running expenses and maintenance of installation.....	2 40
Wages.....	8 78
Dynamite, fuse and caps.....	12 50

Total cost of one meter of heading, including proportional cost of installation..... \$31 98

One drill hit made on an average .82 feet of drill holes, without requiring sharpening. Hardly any repairs were necessary, 2,127 feet of heading being run by two machines in 371 days (including all delays); average progress per day, 5.73 feet.

The average cost of one meter of heading made by the percussion drills was \$59 24, against \$31 98 when the tunnel was driven by the hydraulic drill.

Mines of Freiberg.

"Beihilfe Erbsteinen," in Freiberg Saxony, the percussion and Brandt drills were used, and the following results obtained:

	Percussion drills.	Brandt drills.
Mechan. labor employed 1,453,328 cu. lbs.	1,154,490 cu. lbs.	
Cross-section of heading.....	40 29 feet.	37 29 feet.
No. of holes for 1 attack.....	33 9	6 2
Total length of holes.....	84 06 feet.	22 00 feet.
Cost of 1 running foot of heading.....	\$8 01 9 13	\$7 72

In one minute $1\frac{1}{2}$ inches of a $2\frac{1}{2}$ inch drill-hole was drilled by the Brandt drill in hard gneiss.

Other Mines.

In the mine "Rheinpreussen" the progress made by one Brandt drill in a double-track crosscut was 312 feet per month.

In the mine "Notberg" the average daily progress was 8.5 feet made by one drill.

In "Bleiberg," when natural pressure was obtainable, the cost per one running foot of crosscut was \$4 23, while in "Freiberg," when steam-power was used to run the pumps, the cost was \$8 83. In another mine the lowest price of one foot was \$2 28, and the highest \$13 41.

The cost of running the crosscut from the Albert shaft in the "Plauesche Grund" in Saxony (face 80 square feet) through porphyry was \$8 83, against \$14 85 per running foot when run by hand labor.

The Brandt hydraulic rock drills are now used at a great many mines and tunnels all over Europe, and continue to give great satisfaction.

(CONTINUED NEXT WEEK.)

How to Run a Mill.

The following letter from Superintendent William Irwin has been received at the office of the Bode Consolidated Mining Company, in San Francisco. It shows that Mr. Irwin does not go much on the San Francisco style of doing things:

GEORGE W. SESSIONS, Secretary.—Dear Sir: I understand that there is considerable talk in your city about not getting the pulp assays weekly. If we were working a silver mine it would be all right to do so; but we are working a gold mine, where there is from ten to fifteen per cent of the whole stops in the battery, so that a pulp assay tells you nothing before the monthly clean-up. I am endeavoring to work your mine and keep the mills running at as little cost as possible, but the company (whoever they are) do not seem to appreciate this matter. Hereafter you shall have assays weekly, but you will please bear in mind that neither you nor I can tell from these assays what the ore is paying until the clean-up.

WM. IRWIN, Supt.

THE Northern Pacific has decided to stock and operate the Puget Sound Shore road, viz., the connecting link between the Columbia river and the Seattle road. It will probably be opened for traffic by May 10th.

USEFUL INFORMATION.

Making and Applying Kalsomine.

Kalsomine is composed of zinc white mixed in proper proportions with water and glue sizing. The surface to which it is to be applied should be clean and smooth. For ceilings the following receipt is recommended: Mix one-half pound of glue with 15 pounds of zinc; for walls, one pound of glue with 15 pounds of zinc. The glue, before used, should be soaked over night in water, and in the morning liquefied over the fire. Paris white is often made use of in preparing kalsomine, but it is not so satisfactory as zinc. The mixture may be colored to any desired tint by the addition of suitable pigments. The practical details of preparing and applying the mixture are given herewith from a very reliable source. In case the wall of a large room (say 16x20 feet square) is to be kalsomined with two coats, it will require about one fourth pound of light colored glue and five or six pounds of Paris white (observe our remark above on the use of this material.) Soak the glue over night in a suitable metallic vessel with about a quart of warm water. If the kalsomine is to be applied the next day, add a pint more of clean water to the glue and set the vessel containing it in a kettle of boiling water over the fire, and continue to stir the glue until it is well dissolved and quite thin. The object of treating the glue in this way is to avoid scorching it. Place the Paris white into a large water pail, pour on hot water and stir it until the mixture has the consistency of cream. Now mingle the glue liquid with the whitening, stirring it until thoroughly incorporated, and apply it to the wall with a white-wash or large paint brush. The object to be accomplished is to lay the liquid on smoothly, and a good whitewash brush with long and thick hair will answer very well. In case the liquid is so thick that it will not flow well from the brush, add a little hot water until it makes smooth work. When applying it the mixture should be frequently stirred, and the brush should be inserted into it only so deep as to take up what the hair will retain without dropping off. If too much glue is used the kalsomine cannot be laid on smoothly, and will be liable to crack. The object should be to apply a thin layer of sizing that cannot be brushed off with a broom or dry cloth. A thin coat will not crack. In this connection the following receipt for a whitewash used by the Lighthouse Board of the Treasury Department, and said to answer on board, brick and stone nearly as well as oil paint, than which it is much cheaper, may be found useful. Slake one-half bushel of un-slaked lime with boiling water, keeping it covered during the process. Strain it, and add a peck of salt dissolved in water, three pounds of ground rice boiled in water to a thin paste, one-half pound of Spanish whitening, and a pound of clear glue dissolved in warm water. Mix these ingredients well together and allow the mixture to stand for several days. Keep the wash thus prepared in a kettle or portable furnace, and when used put it on as hot as possible with a paint or whitewash brush. Coloring matters may be incorporated with these several mixtures, as may be required. Spanish brown stirred in will make a pink or red, more or less deep according to quantity. A delicate tinge of this gives a pretty effect for inside walls. Finely pulverized common clay, well mixed with Spanish brown, makes a red-stone color. Yellow ochre stirred in makes a yellow wash, but chrome goes further and gives a better color.

Painting is no Expense.

It must be admitted that the Germans, the world over, are celebrated for their industrious habits, thrift and general economy, and they have a maxim that "painting is no expense." This theory, regarded in a comprehensive view, is undoubtedly correct. An occasional coat of paint on the outside of buildings greatly prolongs their durability, and upon a metallic surface prevents corrosion. It is a matter of doubt, however, whether board fences, on account of being exposed on both sides to the wind, and rain and sun, remain in a sound condition longer by receiving an occasional coat of paint. We have seen them not protected by any substance, standing after an existence of fifty years; and in one instance, the hoard fence, behind which a company of riflemen sought protection when it suddenly fired upon the Hessians engaged in burying the dead after the close of the battle of Germantown, in the graveyard attached to the present Concord school house, on our Main street above Washington avenue, this fence, which was on the ground of the late Peter Keyser, maintained its position, though very thin, with the bullet holes worn to four times their original dimensions, seventy-two years after the battle, never having had, we learned, any paint upon it, as in fact, it was of rough cedar boards. How much longer it stood we are not informed.

Frame houses and barns are often painted dark colors, which are preferable to white in this latitude, as they have a tendency to absorb caloric and render the structures warmer than they would be if daubed with a light or white shade. The whitewashing of walls, fences and buildings produces a tone of neatness, but after a heavy rain or two the original faultless color is decidedly marred. Paint is more durable in its nature, and when applied to

either buildings or farming utensils well repays the expense, and when they are refreshed by an occasional retouching of paint, it is a very decided benefit in appearance and wear, and we commend, therefore, with confidence, the advantages of painting, agreeing with the Germans that "it is no expense."—*Ex.*

INVISIBLE PATCHES FOR FOOTWEAR.—An exchange gives the following as the material used by shoemakers for making what they call "invisible patches." It is a strong water-proof cement, and is prepared by taking gutta-percha, cutting the same into shavings, and dissolving them in chloroform, or in carbon disulphide. The solution should have the consistency of honey, and should be made in the cold, as the solvent rapidly evaporates when heated. When made, for the same reason, it should be kept in a well stoppered bottle. To use this cement, a patch of sufficient size should be made, the edges of the same, and of the place where it is to be, are scraped or shaved down thin, so as to make a smooth surface when the patch is put in place. A small quantity of the cement is spread over the fresh cut surfaces, which are then held near a flame for a few minutes to thoroughly warm the cement and cause it to penetrate the leather. The parts to be joined are then brought together and well hammered down, or clamped firmly in place. The cement dries rapidly by the volatilization of the solvent; and if the job has been properly done, the patch should be nearly invisible, and should make a thoroughly water-proof joint. This cement may be used equally well for patching rubber boots and shoes.

A NEW FEATURE IN PRINTING ART.—A discovery has been announced of a new process which, it is said, will permit of any number of copies to be taken of a book without setting a line of type. A compound has been discovered which may be spread upon a page without in the slightest way injuring the paper. It can be easily removed to a stone, and there becomes the matrix for a stereotype, or can be used for printing from at once. Old books can be reproduced in exact fac-simile, letter for letter, and broken stop for broken stop. The antiquarian will thirst for the blood of this too clever inventor; but practical printers are already moving to see whether they can not save the cost of resetting old editions, and if certain practical difficulties are got over we shall see a change not only in the production of fac-similes of old books, but in the reproduction of modern books. It will no longer be necessary to keep type standing. A proof will be as good as a stereotyped plate. It will be nearly as cheap to reproduce a volume as to print an extra copy of a volume passing through the printing machine.

GOOD HEALTH.

The Philosophy of Coughing.

The following remarks on the rationale of coughing, from the *Journal of Chemistry*, are appropriate and instructive: "Everybody coughs sometimes, and judging by the quantity of patent cough medicines sold, many people must be coughing all the time. Most persons suppose that a cough is a cough the world over, and that what will cure one will cure another; and so they prescribe for themselves and their friends all sorts of syrups, home-made or proprietary, with the consoling assertion that 'it can't do any hurt if it don't do any good.' How do you know it can't do any hurt? Do you know its ingredients, and, if so, have you studied their effects upon the system in health and in disease? Do you know the condition of the patient you are prescribing this for—his constitution, his habits of life, his past history?"

Let us see what a cough is. It is a sudden and forcible expulsion of the air from the lungs, preceded by a temporary closure of the wind pipe to give additional impulse to the current of air. The effect of these spasmodic expirations is the removal of whatever may have accumulated in the air-tubes, whether a foreign body from without, as when a particle of food finds its way into the windpipe, or an accumulation of mucus secreted in the air passages themselves.

Coughing is in part a voluntary act. We can cough whenever we wish to, but frequently we are compelled to cough when we don't wish to. Nerves are divided into two classes, sensory and motor nerves. The former carry intelligence to the brain; they report to headquarters any disturbance on the frontier. The motor nerves then carry back the commands of the general to act. You tickle a friend's ear with a straw, and his hand automatically proceeds to scratch the itching member. A tickling sensation is produced in the throat by any cause whatever; the brain then sends back orders to the muscles concerned to act so as to expel the intruder; in other words, to cough. And that is how we cough.

The source of the impression may be various. Frequently it is due to an irritation of the respiratory organs by foreign bodies, dust and acid vapors, admitted with the air in health, or to damp, cold air itself, if the organs are particularly sensitive, or to the presence of mucus, pus, or blood, in disease. Inflammation, from whatever cause, acts as a source of uneasiness.

There are, as we all know, many different

kinds of cough. Thus we have the dry cough, without expectoration, and the moist cough, with expectoration. We have the short, hacking cough, resulting from slight irritation, and the violent, spasmodic, and convulsive cough, caused by a greater degree of irritation, or some peculiar modification thereof. Then there are the occasional, the incessant, and the paroxysmal cough, terms that explain themselves. Hoarse, wheezing, barking and shrill coughs are due to the tension or capacity of the rim of the windpipe, or other portion of the tube. The hollow cough owes its peculiar sound to resonance in the enlarged tubes or the cavities in the lungs, if such exist. Sometimes the exciting cause of a cough lies not in the lungs and respiratory organs, but in the stomach, liver or intestines. In other cases there seems to be no real cause; it is purely nervous or hysterical.

ARE COAL TAR COLORS POISONOUS?—The trade in coal tar colors was at one time checked by reports that had been circulated respecting alleged poisonous effects produced upon the persons of wearers of garments dyed with these materials. Accordingly, at the aniline color works of Meister, Lucius & Brüning, at Höchst-on-the-Main, where 672 work-people are employed, particular notice has been taken for many years of the health of the employees, with a view to ascertain the extent of the alleged mischief. The products manufactured at the works are very numerous, including many finished dyes of various colors, in addition to nitro-benzol, aniline and alizarine. It is known that nitro-benzol is poisonous, yet among the twenty-four men employed at Höchst, in the nitro-benzol house, during the last four years, symptoms of "nitro-benzonism" appeared in only five cases. Aniline, also, is admittedly poisonous; and of twenty-nine men employed in the aniline house at Höchst, there were eighteen cases of specific aniline poisoning, none of which proved fatal. The workmen in the magenta house, says an exchange, were always reddened with the dye, even to the inside of the mouth, and some of the material must, therefore, have been swallowed; yet not a single case of specific ailment has occurred among them for eighteen years. Neither magenta nor its derivatives, when made without arsenic, can be considered in the slightest degree harmful. Naphthalene is observed to be deleterious only when in the form of hot vapors. On the whole, Dr. Grandhomme finds that the average mortality of the work-people was 4.2 per cent, which is a distinctly favorable result, and should go far to dispel any lingering dread of coal tar colors, on the ground of their supposed possession of poisonous qualities.—*Hatters' Gazette.*

THE CURE OF SACCARINE DIABETES.—In a paper by Dr. G. Felizet, read before the Academy of Sciences, August 14, says the *Journal d'Hygiène*, the author claims to have discovered a remedy for a disease usually regarded as incurable—saccharine diabetes. The author states that he has succeeded in putting an end to glycosuria artificially produced in animals, and that the medicine that suppresses that artificial glycosuria will likewise cure diabetes in a few weeks or months. There exists, says he, a bond of union between artificial glycosuria, intermittent diabetes and confirmed diabetes, and that bond is irritation of the rachidian bulb. It is not then, in masking the disease by submission to the severities of a regime exempt from bread, feculents, sugar, etc., that we succeed in curing it, but by tapping the very source of the production of sugar, that is to say, by suppressing the irritation of the bulb. Bromide of potassium, by the elective action of sedation that it exerts on the functions of the bulb, suppresses the effects of such irritation with a rapidity that is often surprising, and, in large and repeated doses, cures the diabetes.

SIMPLE CURE FOR COLD FEET.—The following remedy for cold feet is recommended by the *Fireman's Journal* for sedentary sufferers, as well as policemen, car-drivers, and others who are exposed to the cold: "All that is necessary is to stand erect and very gradually to lift one's self up upon the tips of the toes, so as to put all the tendons of the foot at full strain. This is not to hop or jump up and down, but simply to rise—the slower the better—upon tiptoe, and to remain standing on the point of the toes as long as possible, then gradually coming to the natural position. Repeat this several times, and, by the amount of work the tips of the toes are made to do in sustaining the body's weight, a sufficient and lively circulation is set up. A heavy pair of woolen stockings drawn over thin cotton ones is also a recommendation for keeping the feet warm."

THE SIZE OF DROPS.—This question derives considerable importance from the fact that many medicines are administered by dropping from a bottle. If it cannot be relied upon to give approximately correct results, it should be abandoned. Prof. C. F. Himes communicates to the *Journal of the Franklin Institute* a criticism of a statement upon this subject, which appears in the latest edition of the "United States Dispensatory." Among the conditions affecting the size of drops, the statement is made that "the drops from a full bottle should be less than from one more or less emptied." Prof. Himes affirms that this statement is erroneous, and that, on the contrary, other things being equal, drops diminish in size as the bottle is emptied, and to such a degree that any one can satisfy himself of the fact in a few minutes

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Calaveras.

STRIKE.—*Mountain Echo*: In the tunnel now being run by George Osborn & Co., in the Gold Hill mine near Smith's Flat, a strike was made last Wednesday which is likely to prove immensely rich. The end of the tunnel is about the center of the hill, about 80 ft. below the surface, and the vein is six inches in width. On last Wednesday they took out \$50, and on Thursday, about the same amount. The last pan that was extracted, yielded ten dollars.

El Dorado.

SLATE MOUNTAIN.—*Georgetown Gazette*, May 2: Mr. J. E. Jordan of the company of Jordan & Zombro of the Slate Mountain quartz mine, which they bonded some months ago to Mr. Monkton, made this office a call yesterday. The work of development on the lode has progressed rapidly, and the extent and richness of the ore is improving. The second payment has been made on the mine by Mr. Monkton. It was bonded for \$16,000, last December, and now the mine could not be bought for \$50,000. Over 200 ft. of drift on the ledge shows pay ore all the way which will average \$20 per ton. The ledge is from 18 inches to three feet wide. It is tapped by a tunnel about 100 ft. below surface. A winze is now being sunk on the ledge at this level to test it 100 ft. deeper. This work of development which will be completed by June, will determine the magnitude of the reduction works which will immediately follow.

Fresno.

COARSE GOLD GULCH.—*Fresno Examiner*: From John Krohn, of Coarse Gold gulch we obtain the following information relative to the mines in his section: The Hawkeye mine and mill on Deadwood is now being run night and day. The mill has five stamps. It was recently cleaned up and gave a heavy yield. The richest ore from the mine is sacked up and will be shipped to San Francisco for milling. The mine is looking fine. Messrs. Rule & McKenzie, owners of the Last Chance mine, started up their mill again on Thursday. They have a large amount of milling ore in their dump, and are continually taking out more. They recently discovered a rich chimney on the north end of their mine. Their old workings are looking as well as usual. Work was resumed on the Texas Flat mine on Monday, and the mill will be started up next week. It is stated that the French Company that have been negotiating with Col. Frees for Quartz Mountain are about to close the sale. Representatives of the Company are now in San Francisco, and Col. Frees has gone down to meet them. If the sale is consummated active work will be commenced at once. A ditch will be brought in from the North Fork of the San Joaquin, a distance of 25 miles, to supply the water for the mine.

Inyo.

CONFIDENCE MINES.—*Inyo Independent*, May 3: Mr. S. A. Densmore, the owner, has been to work on this group of mines for the last 16 years, off and on. They are located in Union district, opposite Independence, and about a quarter of a mile from the C. & C. railroad. In the bottom of the shaft, which is 106 ft. deep, the pay streak is 20 inches wide, carrying 30 ounces silver, 30 per cent lead and \$12 in gold, per ton, from which Mr. Densmore will ship five tons of ore next week to Selby & Co., San Francisco.

COTTONWOOD MILL.—We learn that the work is progressing satisfactorily. Mr. Chalfant said that he proposed to have the mill in running order in two or three weeks, and felt confident that there was plenty of ore out and in sight to keep the mill busy. Deep Spring Valley and vicinity are attracting considerable attention. The season has been so backward that prospecting as well as other industries have been greatly retarded, but as soon as the weather becomes settled we may expect cheering news from this section.

DEATH VALLEY.—The borate deposit interest increases daily. The Eagle Borax Works are working 11 men and keep three large teams steadily employed hauling the product of their mines to Mojave for shipment to San Francisco and New York. The Coleman Refinery employs about 40 men, and turns out three tons of refined borax per day, besides shipping a great quantity in a crude state. They keep nine 18-horse teams steadily on the road between the works and Mojave, a distance of 140 miles. The borax output of Death Valley is at the present time equal to supply the demand of the whole world. Mr. R. Neuschwander a most competent man, has charge of Mr. Coleman's interests in Death Valley. About the first of June work will be abundant at Furnace creek, Death Valley, owing to the intense heat during the summer months and the men moved to Amargosa to work on Mr. Coleman's mines at the latter place.

THE IREN MINE.—This mine situated in the southern end of Death Valley and about 25 miles from the San Bernardino county line, is owned by a Chicago Company. There is a shaft sunk on the ledge to a depth of 80 ft. in ore all the way down. The pay streak is 15 inches wide of ore that pays \$300 per ton. The ore is principally silver, with some copper and zinc. There are 80 tons now on the ore dumps which the Company's five-stamp mill is fast eating up. As soon as this lot is run through a roaster will be attached to the mill before another crushing is made. Eight men are employed in the mill.

WILD ROSE MINES.—Wild Rose district lies about 25 miles east of Lookout, in the southern end of the county. About seven years ago W. L. Hunter, of Lone Pine, located a series of mines in this district—the Argonaut, Junietta, Blue Belle, Blizzard and Virgin. He afterward sold interests in these mines to W. K. Miller and E. N. Medburg, of Lone Pine, and the three partners have since spent thousands of dollars and years of hard labor developing their property. The Junietta has a six-foot ledge which gives an average assay of \$50 per ton. There are 100 tons of assorted ore now on the dump that will yield \$100 per ton. The Argonaut joins the Junietta on the south, and has a ledge of equal size and richness. The Blue Belle is situated about six miles distant from the two former mines.

It has a well-defined 20-foot ledge, and it is claimed the ore will average \$80 per ton. There are now on the Blue Belle dump over 100 tons of this character of ore. The Blizzard and Virgin are close to the Blue Belle. The former claim has a four-foot ledge of fine horn silver ore. Over \$1,000 has been expended on the Blue Belle alone by the present owners. H. H. Welsh, lately returned from that section, informs us that he believes this series of mines are about the best he has seen in the county, and favorably located. There is plenty of wood and water close at hand, and the mines are easily reached by good roads from Panamint and Death valley. At present enough ore has been developed to keep a ten-stamp mill constantly at work for at least ten years.

A RICH MINE.—Within the past few weeks we have published accounts of the Carson mine, near Chrysopolis, furnished by parties interested in the property, and saying that the ore was above the average found in this vicinity. Outside and disinterested parties who have visited the mine lately, inform us that the Carson (formerly called the Eureka) is one of the richest mines in this county, and that the reports given this paper by the owner do not do it justice, by any means. They say the ore is "lousy" with free gold.

YGNACIO NO. 2.—There are two men working on the Ygnacio No. 2, Cerro Gordo, taking out ore. They already have ten tons of silver ore on the dump that assay 100 ounces.

LEONA MINE.—This mine, owned by B. Albert, is located on Yellow Grade, about four miles below Cerro Gordo. The owner has on the dump 53 130 pound sacks of ore, which he will ship next week. Mr. Albert informs us that the assays give an average of \$80 per ton. He also has about two tons of galena ore taken from his mine near the old Union mine, Cerro Gordo.

THE MAXIM COMPANY.—Supt. S. S. Barrie returned from San Francisco yesterday. The company purchased and now have on the way from the Pacific Iron Works all the necessary machinery for a five-stamp mill, which the Superintendent will commence to put up as soon as it arrives. It is expected in a day or two.

THE SAN LUCAS.—There are over 150 tons of good silver ore on the dumps of the San Lucas mine, Cerro Gordo. This mine is owned by R. Lucas, of Lone Pine.

THE ARIES.—M. A. Wheeler has five men employed in the Aries mine, Cerro Gordo, putting it in shape to take out ore.

PROSPECTING.—There are several prospectors in the hills surrounding Cerro Gordo.

Mono.

THE STANDARD SHUT DOWN.—*Bodie Free Press*, May 2: The miners, surface hands and mill-men employed by the Standard Con. Company were considerably taken a back yesterday on receiving their discharge, all in a bunch. At 12 o'clock noon the mill whistle sounded, and the clatter of the stamps ceased, and silence settled down upon the hoisting-works. The news created considerable excitement, for many persons would not have been more surprised to see the sun stop. Small knots of men stood about the streets theorizing as to the cause of the movement, and no two agreed. Some said that the bottom of the mine had fallen out; others that there was too much water to handle, and not a few who talked knowingly of "a nigger in the fence." The opposite side would come in and stoutly assert that the mine is as good as it ever was, and that it contains thousands of tons of good ore that has never been touched. There is a cause for this sudden shutting down of what has long been considered the representative mine of the district; but what that cause is remains to be made public, which will no doubt be done speedily. It is stated that water has lately been so troublesome as to make the extraction of ore difficult and expensive, and until the flow of water subsides the mine cannot be properly worked, as it is almost impossible to get out ore sufficient to keep the mill running. It is also stated that New York stockholders have been very much dissatisfied because of the recent break in the stock, and have resolved to have the mine examined and reported upon by experts of their own choosing, and until this is done it will remain idle. The New York mining papers have been talking in this strain for some time, but what it amounts to only the managers know. The Standard has been a grand mine, and, if it never yields another dollar, will always be counted as one of the best ever discovered on the continent. It has turned out about \$11,000,000 and paid over \$4,150,000 in dividends so regularly every month as to be termed the "Old Reliable." But it is "hid up in ordinary" now, and we can only hope that it may emerge from the present cloud and become as profitable as ever.

DEEP SPRING MINES.—Berry, Broder & Co. are now taking some remarkably rich gold rock from their mine, the Gold Coin, in Deep Spring Valley. Greenly & Co. are at work upon the wagon road to the "78" mine, preparatory to hauling the ore from that and adjacent mines to the mill, now soon to be in readiness for business. The Sam Piper mine, in the same locality, continues to horn out surprisingly rich in free gold.

BODIE CON.—*Free Press*, April 28: There was crushed at the Bodie Con. mill 114 tons of ore, and at the Bodie Tunnel mill, 302 tons. The average assay of the pulp was \$49.87, and of tailings, \$4.70. Most of the ore was taken from the Vulcan vein, which is looking well. To-day they will shut down the Bodie Con. mill for the purpose of putting in the new mortars, which will take about ten days.

MONO.—Since last report the east crosscut on the 260-foot level has been extended 9 ft; total height, 76 ft, with no change to report. The upraise on the Fortuna vein has gained 10 ft; total height, 32 ft. The vein continues about the same width, with ore of the same quality.

BODIE TUNNEL.—On the 200-foot level work is still being prosecuted by contract. They are working on the new vein recently cut, which shows up well—in fact, it is quite encouraging. The ledge is two ft wide.

GOODSHAW.—They are still drifting south on the 600-foot level, making 10 ft during the week. The formation in the face of the drift looks very favorable, and it is anticipated that something good will soon be encountered.

LUNDY NOTES.—*Honer Mining Index*, April 28:

Neptune No. 2, situated on the brow of the mountain west of and overlooking the Old Mono diggings, Jordan district, is now one of the finest prospects in this portion of Mono county. Josh. R. Crane, the well known Bodie blacksmith, who is the original discoverer and locator of Neptune No. 2, has extended the adit or drift 34 ft since January, and the whole length of the cut and tunnel shows from two to three and a half ft in width of clean ore, which ten assays recently made prove to be of good milling quality—in fact, much of the ore is very rich in free gold, while the whole mass carries a good average. Crane and his associates deserve success if any men ever did. Noonan and McCallum's Hyena vein, in the west wall of Lake canyon, nearly opposite the little mill, is showing steady and marked improvement as the tunnel progresses. The tunnel is now in about 154 ft and for the last 12 ft solid quartz of fine quality has been making in rapidly from the bottom of the adit, nearly the whole header now being in quartz giving good prospects in free gold. As this was the only claim in this district that was actively worked throughout the past winter, everybody interested in the district will be pleased at the success of the owners, as it will encourage others to go and do likewise hereafter. Arrangements are being made for the active working of the Bryant mine hereafter. The programme is to work through the shaft the coming summer, extracting and reducing ore as long as the season will permit of outdoor operations, and to drive a deep crosscut tunnel into the vein next winter. By this means could be opened, without expense to the owners, another long idle but valuable mine, for there is every evidence already in sight to establish the fact that the Bryant is fully equal to the May Lundy, both in quality and quantity of ore. The White Cloud a very promising claim, situated on the mountain above the May Lundy, and having a streak of decomposed quartz next the hanging wall that is extremely rich in free gold, is to be actively worked throughout the coming summer. It is owned by W. J. Walker and Wm. L. Callahan. The Great Sierra tunnel, Tioga district, is being driven ahead steadily, without change of formation worthy of note. The work is somewhat retarded by reason of insufficient power of the machinery for the present great length of tunnel, but this will be remedied in time. Two companies are being organized to work quartz in the immediate vicinity of the Old Mono diggings the coming summer—one in Bodie and the other in Virginia City. It is understood that the latter has a mill ready to put upon the ground whenever the prospect will justify such a move. The new five-stamp mill of the Gorilla M. and M. Co., to be erected on Wasson Meadows, at the foot of the company's tramway, has already been shipped from San Francisco, we understand, and the mine is being put in order for a lively run all summer. George W. Esh has resumed work on his Cora claim, just below or east of the May Lundy mine. He is sinking a shaft inclined to the dip of the vein, from which he intends to take several tons of ore for reduction in his arastra. Thomas H. Rule, foreman of the Virginia Creek Hydraulic Mining Company, arrived in Jordan district on Monday last, and will start work as soon as the snow gets off of the ground—early next week, probably. A great deal of prospecting and development work will be done the coming summer in the vicinity of the head of Bloody Canyon, both in Tioga and Prescott districts. There is now a probability that a strong Eastern company will take hold of the Silver Group property in this district some time during the coming summer. The indications are that the Jordan district will experience quite a boom the coming summer, with its gold, silver, copper and hydraulic mines in full blast. Several Bodie people who have mining interests in this district are waiting anxiously for the snow to get off so that they can get out here. It is expected that the Detroit Copper mine and smelting works, in Jordan district, will be started up in a week or ten days. It is said that the Mono Lake Hydraulic Mining Company will begin work at an early date.

Nevada.

DRIFT MINING AT CHALK BLUFF.—*Nevada Transcript*, April 26: A rich strike has been made at the South Yuba Company's cement drift mine at Chalk Bluff, Little York township, and the ten-stamp mill commenced crushing again this week. A rich lead of cement that prospects from 25 cents to a dollar a pan has been found and the management is happy. This lead is supposed to be the same one from which the Brown Brothers are said in times gone by to have taken something like a half a million of dollars, and which also yielded very large returns to various other parties who worked on it at different points. If the indication holds good, from 50 to 60 men will be working in this mine before long. At present there are just enough to keep the mill and hoisting works along from day to day. Jerry Goodwin is doing well with the Birdseye Creek Company's drift mine near by. They are from 30 to 40 men, said to be at work there. Good cemented gravel is coming out right along, and the ten-stamp mill is kept busy crushing it.

THE THURSTON MINE AND MILL.—*North San Juan Miner*, April 26: Last week we visited the location of the Cannon Ball quartz-cracker, recently constructed by Mr. Thurston near Cherokee. It is a wonderful invention. It was set in motion for our benefit and we watched it closely. It is capable of crushing 500 pounds of quartz per hour. That is its capacity and it does good work. The rock taken out of Mr. Thurston's mine looks as though it will pay for working. Free gold was visible in many pieces which we examined and we doubt not that the mill will grow richer at the depth of 100 ft than it is now.

Plumas.

HALLSTEAD LEDGE.—*Plumas National*, May 3: Mr. Jos. Hallstead was in town last Saturday, and tells us that everything looks favorably at the mine. Drifts are being pushed on the ledge, both east and west, and show well. In one drift the ledge is about 15 ft between the walls, and in the other the vein is steadily widening out and looks splendidly. Mr. Hallstead seems highly pleased with the prospects, and perfectly satisfied that the mine will prove as fine a quartz property as can be found in the State.

BUCKEYE STRUCK IT.—From Mr. Hersem of Onion Valley we learn that the workmen in the Buckeye claim, at Sawpit, struck fine pay gravel a few days ago. This is an important strike as it demonstrates that a back channel or bench exists there, and if it proves permanent will place a large value on many claims along the ridge. It has been the opinion of many good miners who were familiar

with that section that a back channel would some day be found, and this strike would indicate that they were right.

San Bernardino.

CONTINENTAL.—*Calico Print*, May 3: We learned from Fred Heber, the principal owner in the Continental claim, that several weeks ago he commenced to take out ore, some of which looks as though it would assay about \$500 a ton. Mr. Heber owns five-sixths of the claim and Abe Whistler, of Daggett, one-sixth. We were informed that pieces of rock from the croppings assayed from \$12 to \$26 per ton. The character of the ore is similar to that of the Bismarck and Humburg. The claim is situated about half a mile north of these mines and in the same belt. Mineral has been found in several places on the surface of the claim, although of a low grade, yet it is sufficient evidence that mineral exists in other points besides the place where sinking has been commenced.

ORIENTAL MILL.—The Oriental mill is constantly at work, principally on King ore, and frequently on custom ore. The mill continues to work beautifully and successfully. Col. E. P. Johnson has become thoroughly familiar with the various kinds of ore in Calico and other districts in this county and is able to treat them most successfully, working the same to a very high per cent.

HUMBURG.—One hundred tons of low grade ore from the Humburg mine have just been reduced at the Oriental mill. The ore was taken from the mine without any assorting excepting the removal of what was considered a very rich chunk of ore. It is reported that the return realized was \$40 a ton, which is a good figure considering the grade of the ore and the immense quantities of the ore that have been taken out and that still remain in the mine.

KEARSAGE.—The Kearsage mine continues to look well. The shaft has been sunk recently about 25 ft and is now down about 70 ft or 150 ft below the apex of the croppings. There appears to be a body of ore several hundred feet in dimensions that has burst upward through a strata of hard, red, barrell rock, and it is calculated that if the ore holds out 50 or 100 ft further down the mine can well be considered a rich and probably permanent one. Messrs. Stevens & McCullough seem to be pleased with present prospects. Work on the invincible mine is still progressing with results most pleasing to its owners. As a result of the work of thirty shifts, five tons of high grade ore were taken out.

Shasta.

ORO FINO.—*Cor. Yreka Union*: Messrs. M. D., Sylvester and John Eastlick have struck a quartz ledge one-half mile north of Oro Fino which they say will prospect \$100 to the ton. They are preparing to erect an arastra on Kidder creek to crush the ore. Messrs. Macaulay and Alford are preparing to crush the ore which they took from the Pinkham & Hull Gulch mine. They are going to use the Shackleford arastras, belonging to Mr. Diggles. Mr. Campbell & Co. are running their placer mine with a full head of water and three giants, and expert miners say that he gets off more ground in one week than our average miners do in a whole season. Having occasion to visit the Bonanza a few days ago I found the mill running on first-grade ore, and all hands busy and in fine spirits. They have been bothered somewhat during the spring months for want of power, sometimes using steam, and at other times water, and then both water and steam. At last they attached what they call the Bonanza windmill, which gives them ample power to run at a rate of 300 revolutions per minute and reduce the ore at a rapid rate.

Sierra.

SALE OF MINING PROPERTY.—*Mountain Messenger*, May 3: The one-half interest of the interest of the estate of B. T. Egglestone in the Egglestone & Mowry mine, Craycroft Hill, was sold by C. C. Smith, Administrator, this week, for \$5,170. The deed was drawn by Attorney F. R. Wehe, signed by C. C. Smith, when the coin was paid over by Lemuel Foss, and the sale was confirmed by the Court.

BALD MT. EXTENSION.—The Bald Mt. Extension Co. at Forest City, cleaned up 140 ounces Sunday. Water was tapped in the drifting works that caused an extensive cave keeping the entire force in the mine for three days on repairs. The main tunnel is over 700 ft in the lava flow. The yield for April was over \$12,500. The Sierra Buttes Co. are operating eight Frue concentrators in the Sierra City mill.

Trinity.

PROSPECTING.—*Trinity Journal*, May 3: Prospectors are beginning to stir about some, and it will not be long before the hills will be full of them, as good weather, for out-door work is now certain. The rich quartz mines discovered in this county during the past few years, and the stoppage of hydraulic mining in lower counties, will give a boom to prospecting in Trinity, which promises to result in many good discoveries. Experienced miners say it is to-day the best field for prospectors on the coast—particularly in quartz. The fact that the ledges already found pay from the croppings down make it an enticing field for men of small means.

NEVADA.

Washoe District.

BEST AND BELCHER.—The west crosscut on the 1200 level is out about 80 ft. The last 30 ft was in very hard rock, but softer rock is now coming in, and the ground has a favorable appearance. An east crosscut will soon be started on this level. On the 2700 level a drift is being run north from the Gould and Curry joint station. This is out 50 ft. It is in birdseye porphyry carrying streaks of quartz.

GOULD AND CURRY.—A drift is being run south-east from the Best and Belcher joint station on the 2700 level. This is out 25 ft. The diamond drill was put into the face and sent in about 40 ft. It tapped a considerable amount of hot water, and also penetrated a body of quartz. The water makes the drift intensely hot, and work has been discontinued to await its draining out.

ALTA.—The diamond drill is still running west from the face of the main west drift on the 2150 level. As soon as the drilling in that direction is completed the miners will resume work in the drift and the drill will be put into the main east drift on the same level, where there are signs of water.

MALE AND NORCROSS.—Work has been discontinued on the 2800 level pending the putting in of a bulkhead to stop the water flowing from the north drift in the Savage on the 2600 level and in the Chollar drift southwest on the same level. The miners have been laid off until these bulkheads are finished.

CHOLLAR.—On the 2600 level the main west drift was turned to the south, when water appearing in the face the diamond drill was put in. A strong flow of hot water was encountered when the drill holes were plugged. A stone bulkhead will now be put in across the drift.

SILVERA NEVADA.—On the 3100 level west crosscut No. 3 is out about 20 ft. It has not yet reached the ore vein. The diamond drill is still being run from the face of the west crosscut No. 1. It shows some water to the west. No work is doing in west crosscut No. 2.

MEXICO.—On the 3100 level the winze has been sunk and timbered about ten ft this week. Its total depth yesterday was about 40 ft. It is still passing down through a mixture of quartz, clay and porphyry.

SILVERA.—Work has not yet been resumed in this mine. The water tapped by the north drift on the 2600 level is slowly decreasing. A stone bulkhead is to be built across the drift.

UNION CO.—The only work doing on the 3100 is in west crosscut No. 2. It still continues in vein porphyry. The east crosscuts on this level are gradually draining out.

YELLOW JACKET.—The usual amount of ore is being taken out on the old upper levels. This is worked at the Carson river mills, which are kept going to their full capacity.

CALIFORNIA.—The east drift on the 2900 level, joint with Con. Virginia, is making about 30 ft per week. Repairs to the C. and C. joint shaft are continued.

ANDES.—Some paying ore continues to be extracted and the prospecting drifts encounter a good deal of quartz of a promising character.

COMBINATION SHAFT.—Are now sinking below the 2800 level. At a proper depth the Cornish pump will be moved down the distance of another lift.

UTAH.—The north drift on the 1950 level has been advanced about 30 ft. The face remains in material showing quartz and porphyry.

BELCHER.—The usual amount of ore is being extracted on the old upper levels, and the mills on the Carson river are kept steadily running.

CROWN POINT.—The usual amount of ore is being extracted, and the mills on the Carson river are kept running to their full capacity.

Belmont District.

BELMONT.—*Courier*, May 2: Have connected No. 3 stop with No. 4 and have the timbers all in place for 95 feet, making a continuous slope of fine ore all ready for taking out, 95 feet in length with 475 feet of backs, this being virgin ground to the surface. Will soon commence repairing the mill, which will require only a few days, as the mill was put in first-class order last season. It is therefore expected to make a speedy and successful run very soon.

Columbia District.

AN EXTENSIVE PURCHASE.—*True Fissure*, May 2: The large lot of base ore which has been piled up and lying on the dump at the Victor was sold the other day to B. G. Smith. It is estimated that there are from 3,000 to 3,500 tons in the lot. Some of it assays over \$500 per ton, though the larger portion is of a base character. The final disposition of the ore has not been determined upon, but it would make a month's run, and on full time, for any twenty-stamp mill in this part of the country.

Comet District.

BEING PUSHED.—*Pioche Record*, April 26: Work is being pushed ahead on the claims out in Comet district. The residents of the districts are commencing to imagine themselves millionaires.

Eureka District.

LOCAL NOTES.—*Eureka Sentinel*, May 3: There are ten tons of ore at the El Dorado mine, on Prospect mountain, awaiting shipment. Messrs. Ball and Poplin are taking out large quantities of flux ore, and shipping it to the Richmond furnaces. There are 100 tons of ore on the dump at the Silver Connor mine awaiting shipment to the furnaces. Fine weather having come with the last change of the moon, prospectors are again getting ready for their season's work. William Harrington is still driving ahead in the new tunnel at the Uncle Sam mine, on Peeltick hill. The breast is now in good ore-bearing ground. Martin Piantoni will put on a small additional force of men in the Dead-Broken mine, as soon as a trail can be sufficiently broken for the conveyance of necessary supplies to the mine. The main shaft of the Queen mine, at Silverado, has been sunk an additional 50 ft, and a new drift has been started from the bottom of it. The tributaries in the Queen are getting some very rich ore. Work on the Lemon mine, which was resumed last December, has been carried on continually since then. The Ivy boys and Harry Rickard have a lease of it, and are shipping ore to the Richmond furnaces. There are now 250 tons of ore at the Fair Play mine in transit to the Eureka furnaces. The property has yielded splendidly during the past year. It has been worked under a lease, which it is hardly probable will be renewed. Some of the tributaries at the Hamburg mine have been forced to suspend operations for the present, on account of the difficulty in getting grub and supplies to the mine, but fine weather having set in, this difficulty will soon be obviated. The tributaries at the Bald Eagle mine are again doing well. They are getting some very good ore, but are unable to ship at present on account of the snow blockade, which has been more severe this winter and spring than during any previous season. At the Alexandria mine water is coming into the main shaft a great deal faster than usual, owing, no doubt, to the melting snow and consequent seepage. The shaft is $6\frac{1}{2}$ x $9\frac{1}{2}$ in the clear, and the water rises daily from 18 to 20 ft from the bottom, which has to be lifted to the surface. There are three drifts now being driven from the main shaft, and other prospecting work is being done with a very fair outlook for striking new ore deposits.

Esmeralda District.

AURORA'S HOPES.—*Walker Lake Bulletin*, May 3: The people of Aurora are considerably elated

over the good prospects of the Silver Lining mine. There is many and old stand-by who has faith that the camp will breeze up again and be as lively as ever. It only needs a start. McKinley & Co. have certainly made a good showing during the time they have worked the Silver Lining, and perhaps others could do as well in other mines if they labored with the same industry and intelligence.

Pinto District.

ORE.—*Eureka Sentinel*, May 3: Andrew Berryman and his nephew, Richard Berryman, are taking some very rich ore out of the Silver Nugget mine, Maryland mountain. They have a good pitch and are making money. A party of miners are taking on out of the Farrow mine, which is situated on South Alhambra Hill. The property is beginning to show up splendidly, and will probably become one of the most prominent mines in Pinto district. The lessees of the Red Rose mine, Alhambra Hill, are taking out some fine ore. The mine is well located and is likely to prove valuable.

ARIZONA.

FROM MINING DISTRICTS.—*Prescott Courier*, May 3: Groom creek district miners are pleased with the outlook. Mr. Clarke is running his mill on ore from the 110 mine, which is yielding more gold than its best friends expected. The management will, we think, soon make an effort to work concentrates at home, as it does not pay to ship them owing to high cost of transportation, etc. Mr. Dan Hatz, who has invested considerable money in mines, has encouraging prospects in several districts. Mines belonging to John Holmes and Mulvennon & Roach, in Turkey creek districts are yielding very rich ores. "Old Grizzly" Callen and his Michigan friend are inspecting placer ground in Weaver district. Mr. Chase, Turkey creek district has several carpenters at work on his mill house. The Pine Spring and Dosoris, two of our richest silver mines, are in good condition.

BONANZA MINES.—*Quitoa Prospector*, April 26: Work on these mines is being prosecuted with the usual steadiness. The outlook continues to be most encouraging. Work has now progressed so far that interesting developments may be looked for at any moment.

PEERLESS.—Tunnel No. 1 is in 148 feet, with no material change in formation. Tunnel No. 2 is in 143 feet. Considerable quartz is coming in on the face of this tunnel.

PEER.—Tunnel No. 3 is in 123 feet, in very lively porphyry, and looks about the same as when our last report was made.

CROCKER.—Tunnel No. 1 is now 127 feet in length, in very favorable formation, deeply stained with iron, and with heavy seams. The rock is more stratified than formerly, and there is considerable heavy spar.

WINZE.—Is now down 72 feet, showing a slight improvement since last week.

COLORADO.

NOTES.—*Georgetown Courier*, April 26: A mill-run from the Vulcan last week returned 411 ounces silver per ton. The Georgetown tunnel will be driven 100 ft further before it cuts the Griffith lode. The Scotia mine is said to be looking well. A recent mill-run went 200 ounces silver per ton. The Pay Rock concentrating works, having been overhauled and repaired, will probably start up this week. Shay & Co. recently had their lease renewed on the Mendota, and will do more extensive work than ever before. The principal work being done on the Cliff at present, is stoping in the lower level. A fair quantity of ore of good grade is being taken out. The snow and ice on Democrat mountain is deeper than known for years. The mouths of the tunnels are blocked, and but little work can be done on a great many of the properties. A double shift is at work sinking on the main shaft of the Cory City. Twenty-five tons of concentrating ore per day will be delivered at the works as soon as they are ready to start. Shay & Co., lessees on the Mendota, shipped three cars of ore last Saturday, or about 30 tons, valued at nearly \$3,000. Myers & Beck shipped one car of 80 ounce ore on Monday. A new party of lessees are sinking from the surface on the Tishomingo. Saline and Co. are putting up a whim and expect to sink their shaft an additional 60 ft. They have a good streak of ore in sight. George Barrett, of the Barrett & Fletcher stamp mill, at Empire, brought over a beautiful gold retort this week, weighing three and a half ounces. It was the product of one cord of ore. The largest retort which he has brought to Georgetown yet was one which was produced last week. It weighed 16 ounces and 13 pennyweights. This retort was the result of one battery's work of five days on three and a half cords of ore. Mr. Barrett says there is but little ore being taken out around Empire now, on account of the heavy snow. The strike on the summit still holds out. We have seen specimens of ore four inches in width that assays 3,368 ounces silver per ton and 48 per cent lead. A lease has been let on the adit level of crosscut lode No. 1, in the breast of which two inches of good ore and 15 inches of quartz is shown. The lessees pay 25 per cent royalty on drifting and 35 per cent on stoping. A lease has also been let to sink a winze from the southwest drift of the 170 level to the 230 level. Drifting and stoping will be done through about 100 ft of ground. Assays made Monday on ore from the 230 level went 1,019 ounces silver per ton.

IDAHO.

EVANS' GULCH.—*Coeur d'Alene Pioneer*, April 28: The wildest excitement was created at Murrayville and Raven last Friday by the reported discovery near the Mountain House of rich pay dirt. The news had scarcely been whispered than 100 men gathered up their effects and proceeded in the direction named. Though the exact locality was not mentioned, the strike was finally found to be in Evans' gulch, a tributary of Prospect creek, only a mile from the Mountain House. As soon as possible pans were got to work and in a short time all were rewarded by a residue of coarse, clean gold, which greatly resembled that found in Bear gulch. The excitement knew no bounds when those present satisfied themselves of the wealth of the new diggings. Each man staked 20 acres, and the news spreading, hundreds more flocked in, until yesterday, when the entire gulch had been located. A town was immediately laid out around the Mountain House station,

and all preparations made to build. A couple of dozen tents are already up, and more will be put up as soon as they can be obtained. The diggings were discovered by William Evans last Tuesday. He had been prospecting for Mr. Truax of Thompson, and intended to come on to Eagle, when the thought of testing this gulch occurred to him. The first pan yielded him 20 cents, so he continued his explorations farther up the creek. That day the result of the repeated panning netted him \$15 in coarse, flaky gold. The discovery was reported to Truax, who came up, and both located claims on the best ground they could find. The news soon leaked out, and the keen instinct of the prospector resulted in the location of thirty claims by last Thursday. Yesterday over 100 claims were on record. Evans & Truax are down six feet, but have not at this writing struck bedrock. Others are getting their sluice boxes ready, and as there is plenty of water and a good fall, we may expect rich developments shortly. About 300 men are already on the ground, and a party just down from Raven reports that he passed nearly 100 men going to the scene of the strike.

SOUTH FORK BOOM.—In another column will be found an account of the Evolution district, organized last week. Since that time a genuine boom has struck this vicinity. Three weeks ago, Mr. Pritchard, who had been worried by constant applications for information about the location of some rich creek of which rumor had it he held the secret, finally gave some instruction to a few friends, telling where they could look for good ground. They finally came to the region described, which was none other than Canyon creek, or the north fork of the South Fork of the Coeur d'Alene river. Pay was found in many places, and all staked claims on the ground. Prospecting continued and the constant influx of others who had got on to the strike, soon filled the country with prospectors, and it was only a few days before Nine-mile creek, only $\frac{1}{2}$ mile west, was found to be equally as rich. Several discoveries were made last week on Nigger prairie—seven miles further west. Hundreds are going to the new diggings, and a town has already been laid out. It is located on a flat between the mouths of Canyon and Nine-mile creeks. Mr. C. B. King, the post-trader, has already sent in a stock of goods, and other supplies are on the way. The town was located by Messrs. Doud, Wallace & Co., who took up 160 acres. The Muller road runs through the new town, which is only seven miles west of Evolution. Mrs. Pritchard is the recorder for Evolution district, and will remove the office to the new town in a few days.

GALENA.—The recent strikes near the heads of Pritchard and Eagle creeks, show that the base metal is well represented. The beautiful specimens of galena which are brought in daily from new strikes, go to show that silver mining will likely be one of the important industries of the Coeur d'Alene country. The galena has a solid, blocky appearance, and resembles the Wood river variety. Though carrying a less percentage of lead, it is equally as rich in silver, and is much more desirable on account of considerable quantities of gold which assays show it to contain. The singular combination of lead, gold and silver, is something rarely met with; but we have it here, and in profitable quantities, too.

THE FINDS.—The variety of minerals which have already been found here is a significant indication of the "possibilities" which this country possesses as a mining region. Besides lead, gold and silver, the metals, manganese, copper, aluminium and zinc, exist in considerable quantities. The fact that considerable snow exists in the places most likely to contain pay-quartz, has restricted operations to the bottoms and low hillsides; nevertheless, the finds here are exceedingly gratifying, and is but a mild fore-runner of what will be found when the mountains are clear of snow.

COEUR D'ALENE NOTES.—Thirty ounces of gold were taken out of the Ives claim during the past two weeks. Mining property in this territory is subject to laborers' lien for the work performed on it. The gold in Pritchard creek is worth \$17 per ounce. In the side-gulches the average is a little higher. In Daisy gulch a great amount of work is being done. A shaft is down 65 ft and shows good colors at the bottom. The Butte Company have got their tailrace up and are ready to begin sluicing. One hundred and fifty dollars were taken out in a trial run. On the Widow claim the sluice-boxes are being set up at the rim of high water, and will be moved to get the channel as rapidly as the water will permit. The "New Comstock" is showing up well. A few men are at work, but the ledge is of such huge proportions that no certain result can be stated for several weeks. The placers on Beaver creek are sure to make a good showing during the coming summer. Eighteen ounces of fine gold were brought in from Beaver during the past week. About a mile and a quarter above Murrayville, on Pritchard creek, a boulder of quartz weighing 25 pounds was found that, for its size, rivals the famous Mother lode slab. It is estimated that \$150 is plainly visible. Two expeditions have gone from Eagle to new finds. The party which left here last Monday are reported on the North Fork of the St. Joseph. The other has got on to the Prospect creek racket and, of course, won't give it away. Bear gulch is a long, narrow gulch, 10 miles in length, and is located for nearly its entire distance. The gravel carries pay and several promising quartz veins have been discovered recently which has redoubled the activity in that section. Several fine specimens are on exhibition. The Mother lode is not the only property containing rich pieces of quartz. Several boulders streaked with gold have been found in various places, and small bits of rich quartz have been frequently met with. On J. C. Baker's claim, at Murrayville, a huge boulder of white quartz was found which is fairly sprinkled with gold. S. F. Mount and others, while prospecting one of the tributaries of the east fork of Eagle creek about six miles from town, discovered old gravel wash near the summit of the divide. The extent of the deposit is unknown, but it prospects well. Several men are at work in the vicinity sinking to bed-rock. Messrs. Porter and Henderson are busy on their various properties. The Gelat claim is being opened up as rapidly as men and money can, but it will be a week or more before all preparations are completed. Messrs. Porter and Henderson believe in getting a good ready and then going ahead. An additional force of six men were put on this week. The Golden Chest quartz vein, belonging to the same parties, located in Fancy gulch, is opening up a splendid variety of quartz, carrying free gold.

The hydraulic for the Webfoot claim in Dream gulch has been put in place. It is 150 ft of six-inch canvased hose, with a one and a half-inch nozzle. The fall already secured is 75 ft, and when the large reservoirs are completed, enough water can be obtained to carry on the work until late in the season. The booming creek now gives a good head of water, and the results will, no doubt, be in the proportion to the increase facilities.

MONTANA.

THE MILLS AND SMELTERS.—*Inter-Mountain*, May 1: The Lexington mills, which produced for the month ending yesterday, about \$95,000, are working on ore from the Lexington and Allie Brown. It pulps between \$50 and \$60 per ton. The old mill, however, is still working, partly on the old tailings dump. The Moulton, which has, until recently, worked considerable custom ore is now working on ore from the mine, and though it is not high grade, it is treated with such admirable economy and skill and there is so much of it available for extraction, that continued profits are assured. The Silver Bow mill is now treating ore from the Grey Rock and Poser, and is contributing between \$35,000 and \$40,000 monthly to the product of the camp. The Howell roaster is doing good work. The Alice mills are now running on a fair class of ore from the Alice and Magna charta, which, together, are producing about 90 tons daily. The best ore now coming out of the properties is that from the south vein of the Alice. The Parrot smelter, one of the best managed institutions in the country, is running exclusively on Parrot ore, of which a vast amount is now in sight in the mine. It is said that the Parrot Co. produces copper more cheaply than any other concern in Butte. The Dexter mill, wet crushing, is making a very successful run on Orphan Girl ore, of which it daily treats 28 tons averaging \$30. The Colorado smelter is working ore from the Gagnon and Nettie, principally, though the Shonbar, Clear Grit, Self Rising and other mines are regular contributors. Six furnaces are in operation, and still another is contemplated. The Belle smelter, which has been closed for repairs for the past few days, is running on a fair quality of copper ore from the Belle mine. Pending developments in that property are expected so to increase the ore output that the other stack in the smelter will be fired up, thus making a demand for at least 60 tons per day instead of 30 tons, as at present. The Montana smelter is working over 100 tons daily from the Colusa, which also produces several carloads of shipping ore. The 400-foot level of the mine shows up magnificent ore bodies, and its product could at any time be doubled.

NEW MEXICO.

MINING AT KINGSTON.—*Lake Valley Herald*: On Friday of last week we had the pleasure of visiting Kingston again and looking in upon some of its representative mines. We found the town looking decidedly dull, and heard many expressions of discouragement. The fact is that the town has always been too large for the amount of mining done—its only resource. The mines never showed better than now, and the smelter has been proven a success. At the time of our visit it was out of blast, but was to start again Saturday morning, after a three days' rest. Three car loads of bullion have been taken out of high grade, and large beds of ore are at hand ready for treatment, while the Iron King mine of itself is yielding nearly if not quite enough to keep up the blast. The Superior is said to be in a fine body of ore, while it and the Bullion are shipping their dumps, the former to Socorro and the latter to Denver; both are getting very satisfactory returns. The Lady Franklin is reported as having a good body of exceptionally high grade ore at 175 ft deep—some of it running to \$18,000 a ton. Work is again in progress on the Miner's Dream. Our visit was but a brief one, and we did not have time to visit either of the above, but we spent a forenoon at the Illinois and Greyhorse. We went first into the tunnel recently constructed; then went above into the shaft and drifts from which the bulk of the ore has been taken, and then examined several surface excavations where prospecting has been done. The shaft is down some 40 ft, at which point a cave in the limestone was opened into. While ascending the shaft one day Mr. Harris noticed a small vein or stringer of ore on the north side, and upon examination concluded to follow it. Within a few ft it opened into a large chamber of high grade carbonates. Other veins were followed through smaller chambers of similar ore until what appears to be the principal vein is struck, having a northwest and southeast course. This was followed with satisfactory results some 45 ft. Finding the indications of permanence satisfactory, Mr. Harris then concluded to open a working tunnel below; he went down the hill in the gulch to the extreme edge of the claim and drove it in through 60 ft of very solid and hard limestone. He struck the vein as anticipated, considerably below the upper workings, then upraised through it and put in an ore shoot, through which the ore is being taken out expeditiously and cheaply. Passing around the point of a ridge, we found Captain Thomas Burns at work on the Greyhorse. He commenced work with two men, gradually increasing to six. He has developed a strong lead of carbonates carrying 30 per cent lead and about 40 ounces of silver to the ton, of which he has taken out some 200 tons. The day before our arrival a peculiar vein of gravelly stuff of a reddish-gray color had been struck, and some four tons had been taken out. An assay of the lot showed an average value of 293 ounces. There is a well defined vein of this rich ore, and, naturally enough, the people of the camp were considerably excited about it. Taking altogether, the mining outlook was never more encouraging.

MINING MATTERS.—*Silver City Enterprise*, May 2: Smith and Tower, of Georgetown, made a shipment of Commercial ore last week. Development work has been commenced on the Hanover mine, Hanover district. Place, Johnson & Co.'s ten-stamp mill at Pinos Altos, will be running about the 20th of May. Elliott & Forbes have made a contract with the manager of the Kingston smelter, to furnish that company with 1,000 tons of ore from their Brush Heap and Andy Johnson mines at that place. Thirty-five tons of ore from the Emma and Hidden Treasure mines, in Chloride Flat, were shipped to Socorro for treatment.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Ahe Co., Black also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. **HALLIDIE IMPROVED ORE TRAMWAYS.** We refer to Gen. Custer mine, Idaho, 5,000 feet Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. Of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. Rivets Hand Driven.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in Dewey & Co.'s SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.]

FOR WEEK ENDING APRIL 29, 1884.

- 297,657.—CULTIVATOR—Daniel Archer, Madison, Cal.
 297,910.—TRACK CLEARER—Ephraim B. Bishop, San Francisco, Cal.
 297,664.—MITER BOX—William L. Boyer, San Francisco, Cal.
 297,668.—TOBACCO SWEATER—George Brownstein, San Francisco, Cal.
 297,594.—STRAW CARRIER FOR THRASHING MACHINES—Maximilian J. Gessner, San Francisco, Cal.
 297,795.—CARTRIDGE IMPLEMENT—Henry T. Hazard, Los Angeles, Cal.
 297,698.—SAW SWAGE—Simon Kinney, San Francisco, Cal.
 297,699.—PIN FOR ELECTRIC INSULATORS—John M. Klein, San Francisco, Cal.
 297,714.—VEHICLE—Jacob Price, San Leandro, Cal.
 297,857.—FIRE ESCAPE—George Sinfield, Portland, Oregon.
 297,647.—SUBMARINE VESSEL—Josiah H. L. Tuck, San Francisco, Cal.
 297,648.—MARINE TORPEDO—Josiah H. L. Tuck, San Francisco, Cal.
 297,734.—WHIFFLETREE—James Whitcomb, San Jose, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

KEY-TAG.—Frank A. Knox, Woodland, Yolo Co., Cal. No. 297,270. Dated April 22, 1884. This invention relates to a new and useful key tag for use in hotels and lodging houses, or other public places, where the keys are constantly used by the general public. It consists in a double tag so combined and arranged that one side shall carry one advertising card, and when fitted together shall present said card on the observe and reverse side. The object is to provide a key tag suitable for containing cards or other printed matter for advertising purposes in hotels, etc.

PISTOL HANDLE.—Jno. C. Kelton, San Francisco. No. 296,412. Dated April 22, 1884. The object of this improvement is to promote a more perfect grip for the band, a means for extending the thumb along the handle in prolongation of the fire arm to produce a more rapid and correct alignment of the barrel on the object, and a recess to screen the little finger to steady the pistol and prevent the muzzle from dropping too low when the pistol is projected at the object to be fired at.

APPARATUS FOR MAKING RINGS, COUPLING LINKS ETC.—Silas Harris, San Francisco. No. 297,258. Dated April 22, 1884. This is an apparatus for the manufacture of metal rings, coupling or other links, and similar oval or circular articles; and it consists mainly of dies so grooved as to receive the link or other article in different positions, so that it may be first formed and partially united and then completely welded and finished at one heat.

FARM GATE.—Edwin D. Rathbun, Williams, Colusa Co., Cal. No. 295,674. Dated March 25, 1884. This invention relates to that class of gates which are opened and closed by the operation of levers on the side of the doorway, and it consists in the novel construction and arrangement of the devices for operating the gate and the latch, and in a peculiar guard to prevent the gate from being opened except by the proper means.

POULTRY FOUNTAIN.—John C. Tappeiner, Bisbee, Arizona. No. 294,932. Dated Mar. 11, 1884. The invention relates to certain improvements in poultry fountains of that class in which water contained in a reservoir is allowed to escape by degrees into a shallow pan. The top of the reservoir is provided with a removable cap and a perforated vessel is fixed or suspended within the reservoir. There are certain combinations of devices which go to make up the invention.

CIGAR BUNDLING MACHINE.—Henry F. Bebnser, Victoria, B. C. No. 297,220. Dated April 22, 1884. This is an apparatus by which cigars may be arranged into bundles and held so as to be tied and prepared for market; and it consists in a combination of devices for accomplishing the object readily.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

Mining Share Market.

The Bodie stocks have been picking up again, though the Comstock shares have not been so lively. The Bodie Con. Co. is said now to have an actual balance on hand, above all indebtedness, of about \$126,000, inclusive of the shipment. This is equal to three monthly dividends of 50 cents per share each on the 77,000 shares of marketable stock, but whether the future dividend shipments will be large enough to enable the payment of these dividends from the reserves in the treasury, is another question. The expenses range between \$25,000 and \$30,000 a month.

The following are the financial balances of the various mining companies on May 1st: Cash on hand—Alta, \$24,658 36; Andes, \$188; Alpha Con., \$6,826 83; Bulwer, \$4,267 20; Bodie Con., \$144,019 88; Best & Belcher, \$2,207 80; Benton Con., \$15,183 19; Con. Virginia, \$56,716 13; Excelsior, \$2,668 42; Gould & Curry, \$22,445 67; Hale & Norcross, \$11,047 10; Mono, \$11,991 73; Martin White, \$5,876 10; Occidental, \$4,010 54; Potosi, \$4,758 01; Sierra Nevada, \$33,176 16; Savage, \$4,793 81; Utah, \$9,212 52. Indebtedness—Chollar, \$840 77; California, \$6,527 81; Lady Washington Con., \$4,093 74; Mexican, \$16,273 71; Ophir, \$19,367 88; Standard, \$11,403 46.

Bullion Shipments.

Hanauer, April 27, \$1,850; Ontario, 27, \$4,916; Horn Silver, 27, \$6,000; Vienna, 27, \$7,650; Hanauer, 29, \$5,750; Horn Silver, 29, \$9,000; Ontario, 29, \$9,797; Hanauer, May 1, \$4,050; Horn Silver, 1, \$6,000; Ontario, 1, \$4,316; Horn Silver, 2, \$6,000; Hanauer, 3, \$3,900; Horn Silver, 3, \$6,000. The banks of Salt Lake City report the receipts for the week ending April 30, inclusive, of \$100,153.13 in bullion; no ore. The receipts for the four months of the year amount to \$1,707,011.25; Bonanza King, 7, \$6,265; Bodie, 7, \$29,866; Contention, 2, \$13,663; Navajo, 5, \$8,000; Standard, 3, \$2,804.

Our Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

Meetings and Elections.

UNION WATER, LUMBER, M. & M. Co.—May 5.—Hon. J. P. Jones, President; Benjamin White, Vice-President; E. W. Marston, W. H. H. Hussey and Samuel Gore, Directors; F. W. Bowen, Secretary.

New Incorporation.

The following company has been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

NORTH STAR M. Co., May 5. Capital stock, \$1,000,000. Directors, M. C. Taylor, W. B. Bourn, J. B. Fargo, D. McKay, Jr., C. E. Clark, J. Gleason and A. W. Thompson.

Pacific Business College.

Many of our readers will remember the burning of Red Men's Hall, 320 Post street, which forced the Pacific Business College of Messrs. Chamberlain & Robinson to take up temporary quarters for a season. Now the rebuilding of the Hall in elegant style has given the college back to its old quarters—the same as before but improved in every way. During the vicissitudes of the college, it has retained its hold upon its students, and the return to the more pleasant and commodious apartments has been the occasion for much enthusiasm and satisfaction to all friends of the institution.

The entire upper floor of Red Men's Hall, 320 Post street, has been constructed on a plan designed especially for school purposes, and it is now one of the most admirably arranged educational establishments in the country. At the head of the stairway, which is lighted by an immense skylight, is the business office. This is a room some 15x20 feet, handsomely carpeted and furnished, adjoining the actual business room, with which it connects.

The Actual Business Department

Is a very commodious room, 48x148, occupying the entire front of the building. Along the eastern side of the room are the banking offices and counting rooms, on either side of the teacher's rostrum. These offices are inclosed by glass partitions, and have the usual conveniences of such offices in first-class banking houses. Fronting these offices, in lines extending across the room, are a large number of elegant and very substantial solid black walnut double-sided desks, each for four students. Towards the rear of the building is the recitation room, well designed for the purpose, and is also well lighted and ventilated. Directly opposite the recitation room is the telegraphic department, which is said by an accomplished electrician to be the best arranged room for a similar purpose ever fitted up on this coast. Occupying the rear or northern end of the building is the room devoted to the theoretical department. This is a very spacious and conveniently arranged room, 48x48, lighted on the east, west and north by fourteen large windows, provided with numerous substantial black walnut desks, and perfect in every appointment.

Each room has the best modern arrangements for ventilation, a drinking fountain, and every convenience which will contribute to the health and comfort of the pupils.

COMPLIMENTARY SAMPLES OF THIS

PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

FOR SALE CHEAP!

Two Sets of

STEEL SHOES AND DIES.

Apply to A. DOBLE,

MANUFACTURERS OF

Sawmill Machinery, Engines and Boilers.

SOLE AGENTS FOR

BALL'S PATENT HIGH-SPEED ENGINE,

Embodying a new, and the only correct, Governing Principle. Valve practically impervious to wear, and almost frictionless. No steam chest. For amount of power economically developed it is, at the same time, the finest and cheapest Engine in the world. One can be seen running at our works.

PRENTICE DRILLS.

PERKINS' SHINGLE MACHINERY,

DELEMATER STEAM PUMPS of any Capacity.

POND TOOL COMPANY'S IRONWORKING MACHINERY,

WILLARD SMALL ENGINES and BOILERS. First-class and Cheap.

CROSBY STEAM GAUGES, VALVES. CHIME WHISTLES, Etc.,

C. B. ROGERS & CO.'S WOODWORKING MACHINERY,

ERICSSON and RIDER HOT AIR ENGINES,

R. HOE & CO.'S CHISEL TOOTH SAWS,

SIGHT DROP CYLINDER CUP.

WE ALSO CARRY IN STOCK:

Shive and Waters' Governors, Best Eastern Leather and Rubber Belt, Emery Wheels, Packing Waste, Etc.

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers. \$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B.—This is Part I of three volumes on assaying by the same author. To be followed by Part II—Gold and Silver; Part III—Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

SPECULATORS and CAPITALISTS, READ THIS!

I know where there are immense deposits of COAL, worth millions of dollars. I need from \$2,000 to \$10,000, or more, to LOCATE, ENTER and IMPROVE said Coal Lands, much of which is upon Government Land. Any person having the money mentioned to invest, can make arrangements with the advertiser to go out with him and see with his own eyes the immense quantity and value of said Coal Lands. I am fully convinced that any party investing in said Coal Lands can, in less than two years, realize at least \$100 for every dollar invested. Any person possessing the requisite means and meaning "business," can address for two weeks, appointing time and place for interview.

A. B. "COAL,"

Care E. R. Robinson, P. O. Box 1474, San Francisco, Cal.

N. B.—The advertiser can show the very highest testimonials concerning integrity and business capacity, and can give good Real Estate Security for as much as \$5,000.

Gold Medals for Best Truss in Existence.

The I-X-L ELASTIC TRUSS has

Cured more cases in the short period of its existence than all others combined during the last century. Has the Universal Joint movement in the Pad (ball and socket adjustable), making it the most positive retainer, combining comfort and ease, ever invented, and performs miraculous cures where all others fail. Indorsed by the Medical Faculty of the world. This Truss is not a magnetic or electrical humbug, but an intelligent RATIONAL CURE TACCS. I-X-L ELASTIC TRUSS CO., Main office, No. 846 Market Street, San Francisco, Cal.

Send for Circulars.

AMONG the late discoveries in the Economic Arts stands prominently that of Engraving by the Art of Photography. While the new methods and processes greatly lessen the cost of producing the special kinds of printing plates most suitably made by the aid of photography, one of the best results gained is the perfect accuracy that is obtained.

Improvements are being continually made through more experienced workmanship, ingenious and wonderful inventions that are exceedingly interesting and useful.

Portraits of men and women are made remarkably perfect in likeness. The same of plants, flowers, fruits, vegetables, landscapes, buildings, etc.

Nearly all kinds of engravings for books, pamphlets, trade catalogues, circulars, cards, handbills, labels, certificates, and other varieties of printing, are made with great advantage and desirability.

Some kinds of illustrations can still best be done on wood, and will long continue to be so made, for various reasons. It is our purpose to use the best available methods for accomplishing economically the most satisfactory results, and work is therefore solicited for all kinds of engraving.

All Publishers, Printers, Societies, Schools, Companies, Scientists, Professional Men, Merchants, Stock-raisers, Horticulturists, Mechanics, Manufacturers, Tradesmen, and all others requiring Engravings, should call and inquire, or write particularly for any further information desired, to the OFFICE OF THIS PAPER.

On inquiring prices, send samples of work similar to that desired, when practicable, or otherwise give as clear an idea as possible of just what is wanted.

Satisfaction guaranteed on all orders.

DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A GOLDEN OPPORTUNITY!

EQUAL PARTNER WANTED.

For the State of California, to furnish means

..... TO WORK THE

Best Amalgamator and Separator

Yet Invented. Patented Oct. 16, 1883.

Will work any material profitably it will pay to dig—Black Sand and Pulverized Free-milling Ore. Little water required; simple in construction; saves all the gold, loses no quicksilver, and requires but a small expenditure of money for immense returns. Investigate, and address the inventor,

GEORGE DEAN,

No. 44 South Morgan Street, Chicago, Ills.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or lift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veinlets of quartz specked with ore. This mine is 1 1/2 miles northeasterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize, excelled by none—yep, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

TO THE LADIES.

MRS. ADCKOCK, having just returned from the East, begs to offer to the public some of the FINEST GOODS ever imported to this coast at prices lower than ever before. An inspection is solicited.

Iron and Machine Works.

MACBETH'S
—PATENT—
STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting.

On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANK SPINNING Co. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.,—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,

For the Mather Lank Spinning Co. (Limited),

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

St. Louis, Mo., Sept. 28, 1883

Messrs. Adolphus Meier & Co.—GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER BUSCH BREWING ASSN.

OFFICE OF Supt. of RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Chief Engineer: In reply to your inquiry of September 24, we respectfully inform you that the three boilers built under your patents under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

(Signed) BRAUCKE.

THE ROLLER ORE FEEDER

Patented May 28, 1882.]

This is the best and cheapest Ore Feeder now in use.

It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

NO. 7 IMPROVED

AIR COMPRESSOR.

SPECIAL ADVANTAGES.

Absolute certainty in the action of the valves at any speed. Perfect delivery of the air at any speed or pressure. The heating of the air entirely prevented at any pressure. Takes less water to cool the air than any other Compressor.

Power applied to the best advantage. Access obtainable to all the valves by removing air chest covers. Entire absence of springs or friction to open or shut the valves. No valve stems to break and drop inside of cylinders.

Have no back or front heads to break. The only Machine that makes a perfect diagram. No expensive foundations required. Absolute economy in first cost and after working.

Displacements in air cylinder perfect. Showing less leakage and friction than our competitors and a superior economy of about 20 per cent.

Small Sizes made in Sections not to Exceed 300 lbs.

With Adjustable Cut-off Poppet Valve Engine, and Forced Iron Crank Shafts.

WORTHINGTON MINE PUMP.

ALEXANDER L. HOLLEY, being duly sworn, says: I am by profession a civil and mechanical engineer. I have been especially employed during the last ten years constructing and managing works for the manufacture of Bessemer steel. I am now Consulting Engineer to the Bessemer Steel Works of Troy, the Cambria Iron Works, the Bethlehem Iron Works, the North Chicago Rolling Mills, the Joliet Iron and Steel Works, and the Edgar Thomas Steel Works. In all Bessemer Works the hydraulic machinery is the most expensive and the hardest worked part of the plant. Any delay or serious fluctuation in its operation is fatal to the commercial success of the Bessemer process. After extensive acquaintance with the WORTHINGTON ENGINES, and with all such other forms of pumping engines as have been applied to the purposes required, I have adopted it exclusively, and to my knowledge it is adopted in every Bessemer works running or building in America. I have also, for the same reasons, adopted the WORTHINGTON PUMPS for feeding boilers.

Will contract to raise any required height single lift with our NEW PATENT MINE PUMP. Recent practical tests in Deep Mines of Mexico demonstrate this to be the BEST MINING PUMP extant. At the largest stock of PUMPS for all purposes west of New York at our

BRANCH HOUSE, 30 and 32 First St., S. F.

and SEVENTY-FIVE DOLLARS
(\$575.00).

THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

SAN FRANCISCO, SATURDAY, MAY 17, 1884.

VOLUME XLVIII
Number 20.

American Blast Furnaces.

The whole number of furnaces in blast in this country on April 1st was 269, as compared with 288 furnaces January 1st. It is, however, right to remark that the aggregate productive capacity of the furnaces in blast April 1, 1884, was \$5,561 tons, as compared with \$3,325 tons April 1, 1883. There is still a larger number of furnaces in operation in the United States, than were in blast in the stagnant spring of 1879, when 241 furnaces were at work. The number of American furnaces out of blast April 1, 1884, was 432, as compared with 334 furnaces at the corresponding date of 1883. The productive weekly capacity of the furnaces in blast in the United States April 1, 1884, may be summed up as follows: Furnaces worked with charcoal, 8,713 tons; furnaces worked with anthracite, 27,612 tons; and furnaces worked with bituminous coal, 49,236 tons. It follows that the aggregate weekly capacity of the furnaces in blast at the commencement of April, 1884, was \$3,561 tons, or at the rate of 4,449,172 tons per annum. The productive weekly capacity of the furnaces out of blast at the commencement of April, 1884, was \$2,679 tons, so that we may sum up matters in general terms, by stating that the blast furnaces of the United States are now only worked at about half their whole strength. Pennsylvania continues, of course, the great stronghold of American metallurgy. The furnaces in blast in Pennsylvania at the commencement of April, 1884, had altogether a productive capacity of 41,662 tons, so that very nearly half the pig iron, which is now being made in the United States is being produced in the single State of Pennsylvania. Ohio is also turning out a large proportion of the pig now being made in the United States, the bituminous coal-worked furnaces of Ohio at present in operation, having a weekly capacity of 8,132 tons. The productive weekly capacity of the furnaces in blast in New England is at present 560 tons; in New York, 5,882 tons; in New Jersey, 1,452 tons; in Maryland, 850 tons; in Virginia, 2,140 tons; in West Virginia, 2,410 tons; in Kentucky, 90 tons; in Tennessee, 2,790 tons; in Georgia, 884 tons; in Alabama, 3,590 tons; in Illinois, 7,400 tons; in Michigan, 2,578 tons; in Wisconsin, 1,535 tons; and in Missouri, 2,200 tons.

HYDRAULIC PUMPS.—A hydraulic sinking pump, of the pattern designed by Joseph Moore of the Risdon Iron Works, of this city, several of which are in use on this coast, has been built in Glasgow for use in a Scotch colliery. The pump is to be placed 600 yards from the engine on the surface. The pressure on the pump plungers will be 310 pounds per square inch, and the pressure on the power plunger 750 pounds per square inch.

Handling Safety Lamps.

In handling safety lamps in coal mines an expert says that every lamp should be examined before leaving the lamp cabin, and if suitable a lamp cleaner appointed, who will see that no lamp is unfit for duty, being sent down the pit; to be again examined before leaving the lower station, to see whether any accident has occurred since leaving the lamp cabin, and securely locked by the overman or some responsible person appointed for the purpose. A shield should be attached to each lamp, to slide up to and from the top ring of the lamp. The shield should be square cut, and when down should extend to about 2 in. from the top of the lamp, so that when traveling against the air the

Side view, showing drilling spindle in vertical position

Cobalt and Nickel.

We had a conversation this week with Mr. George Lovelock, of Lovelock Station, Nev., who is in San Francisco looking after the crushing and sampling of some ore he has brought with him from a mine recently opened. He brought down 15 tons of ore, analysis of which shows it to contain 12 per cent of nickel, 7 per cent cobalt, and 29 per cent of arsenic. Samples from the same mine, tested in New York showed a result of 28 per cent cobalt, and eight per cent nickel. The arsenic is worth about 20 cents a pound when out of the ore and in marketable shape. The variety of ore is known as "cobalt bloom." It was crushed and sampled here, but there is apparently

Front view, showing drilling spindle in horizontal position.

WARREN'S BALANCED SPINDLE RADIAL DRILLING MACHINE.

flame will oscillate as little as possible, and when slid up a good light will be given all round the lamp. Should any lamp be rendered unsafe by having oil spilt on the gauze, or defective in any way whatever, the flame to be extinguished by gently drawing down the wick with the pricker, taken to the station and examined. At the appearance of firedamp the flame should be dealt with as above; on no account attempt to blow it out, as by so doing the flame might be forced to pass the gauze; or shroud the lamp in a jacket and carefully remove it—proceed to the station and give the report. No one should be allowed to continue work where such indications have been seen. Any interference with the lamp beyond trimming the light should be prohibited, and any one witnessing the same should report to the person in charge. Proper supports should be provided for the lamp, and not to be nearer the revolution of the pick or other implements than 3 ft. No lamp should be passed until cleaned and every aperture seen through.

A PROCLAMATION in the Victoria Gazette throws the island lands open to settlement from the first of next month at \$1 per acre.

no market for it in San Francisco, or at any rate no one here seems to care to undertake to work it. There is a regular ledge of this ore with "iron" walls on one side and gypsum on the other. The main ledge is 8 feet wide and adjoining it is a very large ledge or deposit of gypsum 200 feet wide. This has several veins and stringers of ore from 6 inches to 3 feet wide. On the main vein they are sinking an incline following the ore down. These veins are in the East Range of the Sierra, in Table Mountain District. The mineral region extends down southerly as far as Stillwater, the county seat of Churchill Co., Nev. The country is full of mineral, though few mines have been located. Mr. Lovelock says there is copper, nickel, lead, silver, etc. The range is thickly timbered and there is plenty of water. The particular place referred to is 40 miles from Lovelock station, where Mr. Lovelock has some copper property of value also.

The Belknap trail has been completed to Eagle City. Freight is now carried over this route at 8 and 10 cents, traffic men guaranteeing all freight to go through in two days. Passengers fare is \$12.

The Warren Drilling Machine.

The engravings on this page represent the Warren latest balanced spindle five-foot radial drilling machine. There are only two of these machines so far in use on this coast. One of them is at the Central Pacific Railroad shops in Sacramento, and the other at Joseph Enright's, San Jose. The balance weight runs on planed grooves, and requires no adjustment in the position shown. The greatest distance from the center of the upright shaft to the center of the spindle is 56 in.; bead traverse on arm, 36 in., and the arm radiates a complete half circle. The distance from the spindle in its highest position to the floor table is 64 in., but it may be lowered to 15 in.; the arm is raised and lowered by power. The head is moved on the arm by means of a hand wheel, so arranged with gears and rack that the operator can move it quickly, having the advantage of being over his work instead of using the screw at the end of the arm. The steel spindle is 2½ in. diameter, 14 in. traverse, driven by 3½ in. belt, on a cone of four changes; back gears six to one, with double power in head, and spindle varied by eight motions. The arm can be turned to any degree, as it swivels on a graduated shoe A, which is planed on tracks on the vertical bed B, secured by four large bolts. The utility of having the shoe planed on tracks is manifest. When the operator desires to throw the arm over and drill in a horizontal position, he can raise and lower the arm to accommodate the drill and counterbore, and yet retain its exact position with the work. The quick return

and feed act the same in all positions. The great distance between bearings on the vertical bed, B, obviates the necessity of tightening and loosening the grip bolts on any surface drilling, thereby saving a large per cent of time. C is a portable table, which can be readily detached, and large work placed on the floor table, the extreme dimensions of which are 102 inches long, 32 inches wide, provided with three slots. On the back of the floor table a bearing 32 inches long, 6 inches deep, is planed true with the table, to admit of a T extension. The shafts are steel and bearings long and large. The shipping weight of this tool is 6,000 pounds. The Berry & Place Machine Co., 8 California street, are agents for this coast.

THERE is much uneasiness in the Northwest Territory, many Indians having left their reservation. The trouble is attributed to the swindling operations of Canadian and American officials, and the furnishing of provisions to the Indians unfit for food, and which have caused much sickness and death among them.

THE United States flag-ship *Hartford* is at San Pedro with one of her cylinders broken.

CORRESPONDENCE.

Warranted, unendorsed, opinions of correspondents.—Eos.

Stoppage of Gold Mining.

[Written for the Press by ALMARIN E. PAUL.]

When we analyze the action of European nations, and our own people as well, there seems to be a very anomalous condition of ideas as respects gold. In Europe and among the bankers of our own country, there is a desire to have only one metal for a currency—to wit, gold, and at the same time there is a settled tirade against mining for the very metal they seem to think only suited for a circulating medium.

This paradoxical condition is greater in California than elsewhere in the world. Here all values are based on gold only, and here the effort to destroy gold mining is more deep-set than anywhere else, so much so that we may say one decision of one very wise judge will cost the people of this State one hundred million of dollars before the ruinous effects of it are fully overcome. That we are moving on to a financial crisis is as certain as that silver mining is being destroyed by the heavy discount and tirade against silver as a currency; that gold is transported to Europe by millions weekly; that gold mining has no favor in the eyes of the banker, who should foster it, and that gold production is declining the world over. The decline in our gold production is to-day seriously felt in San Francisco, and many say in the whole State. The interior banks are so pressed, in consequence of their support of the wheat interest at the expense of gold production, and wheat proving by sale an un-gold producing crop, they now call on the San Francisco banks for loans of gold to carry them through. They may get help to a limited extent, but this will not mend matters. Gold has got to be returned. Pay-day will come, and wheat is not gold as formerly, except at unwholesome figures disastrous to farmer, merchant and the country banks. To-day the gold miners of California hold a great power in their hand, for if they were to store the gold they produce, and not allow it to enter the channels of business, they would soon set business men to thinking, and soon there would be a cry for undoing the villainous laws that have ruined so many hard-working miners. I do not advocate such a course, and yet it would be a just retribution for the injury enacted. Of all the States California should be the most prosperous, from the fact that her mountains are stored with the most valued metal, and yet the laws, courts and her own people spend their power and money to prevent production and to keep mining capital away from investing in her gold-producing properties, making a double loss, money for investment and money from production. As water will find its level, so will all this find its balance in the distress which the lack of production will bring about.

Let me ask: Suppose gold miners the world over should stop mining for five years, what would be the result?—Universal stagnation of business, riots and civil wars. The per centage of poverty and labor troubles is in the same ratio as the lack in the production of gold, as long as gold is the standard of values. California business is suffering greatly now, and every bank and business house in the country is going to pay the penalty of this non-production, the sooner they realize this fact the sooner will there be prosperity. An illustration of this whole idea may be found in Nevada county, where a whole section is mostly depopulated by the late decisions. Those who do remain are idle, yet necessarily consumers. Business is ruined and there is no production. Draw the contrast with a large population, active and with "clean ups," of from \$100,000 to half a million a month.

To take commercial statistics, there are over fifty ships in the port of San Francisco idle—as we have no paying freight for export—wheat as prices rule is as dangerous to the financial safety of any business firm as dynamite. Wool is dull from over supply and so we are getting badly worsted. Our wine interest may be profitable in one sense; but if it brings gold how much goes to the account of idleness, pauperism, insane asylums, prisons, prostitution, suicides and murders.

We have lost the northern trade to a great extent, and perhaps soon the English, India and China transfer trade may go by the new Canadian line across the continent. Thus with all our industry and advantages of climate etc., we keep getting back licks faster than is pleasant. The sooner there is a general taking account of stock as to what we have for profitable shipment to enrich ourselves from, the sooner will all appreciate the fact that gold production is the most valuable and certain of all. We don't have to run far to get wealth from it—it is king of all.

LADY BRYAN.—The new hoisting works that are being put up by Hon. C. C. Stevenson on the Lady Bryan mine, Flowsy District, will soon be ready to start up. The building is up and nearly all the machinery in place. These works are being put up on a south chimney of the lode in which no work has heretofore been done, and where a great amount of paying ore has been found immediately upon the surface.

Metallurgy of Nickel.

(CONCLUDED FROM LAST WEEK.)

Christoffe, of Paris, had just erected extensive works at St. Denis, and had made a most brilliant display of his products in one of the main avenues of the exposition. The Vivians, of Swansea, and other exhibitors, had large cases filled with beautiful objects of hollow and solid ware of nickel-silver. Amid these various exhibits of striking *tours de force*, the modest little show-case from the United States, with examples of manufactures of pure wrought nickel, not alloy, could hardly be expected to excite attention and win the golden award which was most cheerfully accorded as soon as the fact was demonstrated by analysis that the objects were really of the pure metal. Some of the objects shown at that exhibition have retained their brilliant polish and luster unimpaired to this time, without being rubbed or cleaned. These notable advances in the metallurgy of nickel, made with the leu and sulphureted ores of Lancaster Gap, prepared the way for greater advances. Dr. Fleitmann, of Iserlohn, Westphalia, Prussia, who was for a time engaged at the works in Camden, has improved and cheapened the operation of refining nickel and toughening it, and has reduced the liability to the presence of blow-holes in castings by adding to the molten charge in the pot, when ready to pour, a very small quantity of magnesium. This is immediately decomposed, magnesium is formed, and graphite is separated. It would seem that the magnesium decomposes the occluded carbonic oxide, or reduces it to a minimum.

The magnesium must be added with great care, and in small portions, as it unites explosively with the charge. It is stirred in. About one ounce of magnesium is sufficient for 60 pounds of nickel. Three-quarters of an ounce to 54 pounds of metal has been used with success by Mr. Wharton. The nickel from the ore at Lancaster Gap seems not to require as much as the foreign metal. It is to be noted that complete malleability of nickel was obtained at Wharton's works in Camden before Fleitmann's invention or process, but this last is more rapid and better than the old method. Nickel so treated with magnesium has been rolled into sheets as thin as paper. The metal becomes remarkably tough and malleable, and may be rolled into sheets and drawn into wire. Cast plates can be successfully rolled. The cast plates, such as are made for anodes, after reheating, are rolled down to the desired thickness. It is found that it is a great improvement to the nickel anode plates to roll them down. They dissolve with great uniformity in the bath, and do not crumble away in the wasteful and annoying manner of cast anodes.

Expensive works for rolling nickel have been recently erected at Camden, containing among other machinery two trains of 40-inch rolls 18 inches in diameter, with annealing ovens and their adjuncts, and a 90-horse power engine. At present this mill as well as the works for producing the metal, and the mine, also, are shut down, and have been since January 1, 1883. The largest sheet yet rolled at Camden was 72 inches long and 24 inches wide, of pure nickel.

Dr. Fleitmann has also succeeded in welding sheet nickel upon iron and upon steel plates, so as to coat them equally on each face with a layer of nickel. The quantity preferred by weight is 8-10 iron and 2-10 nickel, 1-10 of nickel being placed on each surface. To secure union, the iron or steel must be perfectly flat and clean. A pile is made with outer facings of sheet iron to protect the nickel from scaling. When the whole is heated to the proper degree, it is passed through the rolls. The two metals become so firmly united that they may afterwards be rolled down two or three together, or separately to the thinness desired. At the recent meeting of the Institute of Mining Engineers at Boston, a full series of examples of forging and rolling nickel was shown. Samples of rolled metal were exhibited cut from sheets made at the Camden works. These consisted of one sample, No. 20 gauge, 10 per cent nickel; one sample, No. 22 gauge, 10 per cent nickel; one sample showing edge of sheet. These were all examples of nickel upon iron. There was also shown a thin sheet of pure nickel annealed.

The physical properties of the two metals—iron and nickel—are so nearly the same that they work well together, and they adhere tenaciously. The nickel surface cannot be removed or regained in the scrap and waste except by dissolving out the iron core by dilute sulphuric acid. In the earlier experiments the ingots, or cast plates, were beaten under the hammer; this produced a great deal of scale and waste, as with iron, but this is now avoided, partly by the device of a thin covering of sheet iron, which is afterwards dissolved off. Dr. Fleitmann claims to have produced steel wire similarly coated, and proposes to make nickelled boiler plates.

The applications in the arts of such nickelled iron sheets will readily suggest themselves. Up to this time the most direct uses seem to be in making hollow ware, particularly ordinary vessels. The manufacture of such ware has already begun at Schwerte by Dr. Fleitmann, and a great variety of vessels, such as saucepans and kettles, have been turned out, some of them of pure sheet nickel. They are all very beautiful in appearance, resembling highly-finished platinum vessels more than ordinary ware. When

planished and buffed off, the surface becomes like a mirror and will answer the purpose of one. The vessels already sent to this country as samples are made of nickelled iron, and show the facility with which the compound sheet metal may be stamped, spun up and polished. This ware is far superior to tinned iron or tin-ned copper for cooking in. Experiments have shown that it is not poisonous.

The nickel is not only less liable to corrosion, but is harder, will last longer and cannot be melted off by overheating. The ware is lighter and stronger than tin or copper ware; is susceptible of a high polish, and is not easily tarnished. It is well adapted to the manufacture of dishes, salvers and covers for the table. The coating of nickel applied by welding is stronger, tougher than that deposited by electrolysis, and appears to be less liable to scale off. The electrically deposited metal is in some cases very brittle, and no doubt contains sufficient hydrogen to essentially modify the physical characters of the coating.

This new application of nickel constitutes practically a new industry of great importance. It increases the consumption of nickel, and will stimulate its production, and by giving a steady demand will no doubt lead to a more uniform and constant supply.

Placer Prospects.

Gold is found in all the gravel beds along the eastern base of the high Sierra, from the Big Meadows, north of the old Dogtown diggings, to the gorge through which Owens river passes from Long to Round valley, a distance of about eighty miles. Gold-bearing gravel beds interstratified with quicksand are found on the high mountains of massive clay lying between Mill and Lee Vining creeks, and overlooking Mono Lake. Some of the latter beds are 10,000 to 11,000 feet above sea level and from 3,000 to 4,000 feet above the subjacent valley of Mono Lake, and are of precisely the same character as those found at depth in Rancherie gulch, on the east flank of the Old Mono diggings. The old Dogtown and Mono diggings were fabulously rich; good pay was obtained along the gulches between Lee Vining and Bloody Canyon creeks, and between the latter and Parker canyon. Rush creek—next south—heads up in the lava fields, where one arm of the great primary volcanic fissure of the eastern slope rent the summit of the range obliquely from the main parallel fissure to the head of the North Fork of the San Joaquin, and buried or vitrified the gravel and placed the metal beyond the reach of man. The same may be said of Deadman's creek, the main tributary of Owens river, except that Deadman's emerges from the scoria and ash into the gravel zone before reaching the valley. In consequence of this lavatic outpour—evidently occurring subsequent to the deposition of the gravel—there is a break in this auriferous gravel deposit, extending from Rush creek to the canyon leading up to Mammoth City. South of the last-named point, however, it reappears and extends for many miles, coarse gold (one chispa worth \$5) being found about the mouth of Convict canyon. The southern end of this gravel range has scarcely been looked at, the few prospectors who have explored that uninhabited region having confined their operations to the higher mountains, in search of quartz. Doubtless some day rich diggings will be struck at several points along this range, and hydraulic streams leap from every canyon, and sluice streams from every ravine and gulch.—*Homer Mining Index.*

GLOOM IN PATTERSON DISTRICT.—A correspondent writing us from Clinton, Patterson District, in the north-western portion of Mono says: "This has been a tough winter in this section. There is lots of snow here yet. There is very little doing in Patterson District at present. There are five or six men working at the Silverado mine, about four miles from Clinton, and some men have come out to put up a mill for the Silverado. I understand it is to be a 5-stamp mill. The Summers mill and mine were turned over to their creditors, and it is about all the people here can do to live. The crash came with the heavy snow storms, when the people were out of grub and could not get out anywhere to get any, and the storekeeper closed his store to those who were without money; consequently they were left in a bad fix. I believe the Summers mine trouble has now been settled. They have issued stock to the amount of about 100,000 shares. There are between sixty and seventy shareholders in the concern, the stock being issued at thirty-five cents per share. Eight or ten men have taken a contract to take out ore from the Kentuck (Summers) mine, to be crushed at the Summers mill. The contractors are to pay for the packing, and get half the bullion as it comes from the mill. I understand the proposition is to run the Summers mine and mill this summer, but the Kentuck mine is gouged out in such a manner that it is difficult to get out any ore without a great deal of expense. I have also understood that there is to be a mill put in Sweetwater Canyon some time this summer, but the way things look now I don't think there will be much progress made in Patterson District during the current year. I have been in a great many camps since I have been on this coast, but this beats them all. There is not a dollar here nor any show to get a dollar." *Homer Mining Index.*

Political Malaria.

Eternal vigilance is the price of liberty. What does it avail if our ship of state be stoutly built and on the finest model, if the captain be incompetent or in collusion with the pirates, and the crew drunk? The decay of all great States has begun at the height of prosperity, just when, to all outward appearances, they were entering on a long and glorious career. Great revolutionary excitements are apt to be followed by a season of repose, when patriotic vigilance, from a sense of safety, falls asleep. While Greece was building the monuments of her brave dead upon the battle fields of Salamis and Marathon, decorating in poetic lays the memory of their heroic deeds, giving herself up to the most daring commercial adventures, the fascinations of pleasure, polite learning and the elegant pursuits of art and literature, corruption was silently eating at the core of her Government, and when at last the voice of Demosthenes awoke the people from the spell of lassitude and indifference, it was too late. We have much to be grateful for as a people. Our country is prosperous at home and honored abroad. Our credit is unparalleled. And then we are in the gulf stream of the world's political thought, and it ought to be a matter of just gratification that our nation has taken the lead in the movement. But we seem to need an occasional scandal in high places to awaken the apathy of public sentiment to the need of a high moral integrity in our public men. The ease with which unscrupulous men get into power and gain control of public affairs is the only great danger that is apparent in our Government. The apparent indifference and unconcern with which the people trust the property, reputation, marriage, chastity and the public weal to men boorish in manners, ignorant, unable to manage their own affairs, notoriously given to animal indulgences, crafty, selfish, rapacious, and in the market ready to be sold to any bidder, is amazing. Let us see how this matter concerns us all. The men we place in public trusts become the exponents of public virtues. They are representative men. Wherever they go their shadow falls to heal or hurt. In every town, and city, and community they are in some degree looked up to and consulted by their constituency. The young men look to them for example, and the old men quote them as oracles. No man, no matter how small he is—and some of them are quite infinitesimal—can be hoisted upon the pedestal of office and public favor and stand there as harmless as a marble statue or the wooden Indian before a cigar stand. His character for good or ill will be felt in spite of him. Now, if that man be mean, low, coarse, vulgar, a double-tongued trickster, an unprincipled time server and wire-puller, a thieving scoundrel, he will harm the public morals on a wider scale, and diffuse the subtle poison of his own example more thoroughly and fatally than a bad man possessed of more intellectual power and grace of manner out of office, just because his position is more public and noticeable. And one of the most painful facts in connection with this matter is the almost universal apathy of the masses to the moral conduct of their public functionaries. Why, it has passed into a proverb with many that we should not expect and require as high moral honor and integrity of politicians as we do of business men. That men under congressional and legislative formalities, in caucuses, handling the ropes of an election or dispensing public patronage, may do for themselves, their friends and party, what in the common interchanges of social life and in business relations would be denounced as indecent and dishonorable.

Very few of our public men escape the taint of the malaria. It is notorious how many of them come home hemmied in honor and principle, and skulk round to the ring-tailors and political boot-blacks, to be brushed and shined up for another campaign. The fact is the average politician will steal if he gets a good chance; and this state of things cannot be remedied by merely turning out one party and putting in another, for the men of all parties possess the same passions, aims and ambitions, and under the same pressure of circumstances will do the same things. We can hope to see an improved state of political morality only so far as the mass of the people rise above all party feeling, all traditional prejudices, all local and selfish interests, and shake themselves free from all cliques, rings and drill clubs; so far as in generous rivalry, see which side can excel the other in producing the best men for office, men with the finest brain and culture combined with the most fixed and substantial habits of honor and integrity.

MINING IN NEW MEXICO.—There has never been a brighter outlook in mining industry than at present in New Mexico. The different machinery for the reduction of the ore is in full blast in mining centers, and high grade ores seem to be the rule. New Mexico is attracting the attention of mining men of Colorado, California and all old mining regions from the fact that our ores are rich, easily worked, and the climate all that could be wished for, no late springs or severe winters. New Mexico is on the eve of a very extraordinary successful mining career, and one that will be lasting.—*Las Vegas Gazette.*

MECHANICAL PROGRESS.

Grecian Stone Cutting.

A rather interesting observation has recently been made upon the methods of stone cutting employed by the ancient Greeks. Every one knows that the marble blocks of which the Grecian masonry was composed are put together without mortar, and so nicely fitted that in many instances two adjacent stones have, as it were, grown together by the cohesion of their particles, brought into almost absolute contact, a fracture made by a blow upon one passing directly into the other, just as if the two formed a single block. With regard to the fitting of the drums of columns, Mr. Penrose, the most scientific and practical of all investigators of Greek architecture, believes that the desired effect of close-fitting was obtained by inserting a wooden pin as a pivot in the drill holes which are always found in the centers of the drums, and revolving each drum upon the one below it, first placing sand between the stones until a perfect joint was obtained, in the same manner that glass stoppers are ground into bottles, and pieces of metal work of certain kinds fitted to each other. This explanation, which is probably the true one, solves the problem completely, so far as the drums of columns are concerned, but throws no light upon the fitting of the other stones of the Grecian buildings, such as the blocks of the entablature, which are found to have joints as close as those of the columns, the edges of each block, for a certain distance back from the face, being polished, while the rest of the joint is slightly sunk, in order to allow the polished portions to be brought into perfect contact. As no sign of a pivot can be discovered on the stones, even if it were possible to revolve them in contact with each other, it is plain that a different process must have been used for fitting them, and an inscription discovered a few years ago gives us some idea of what the process may have been.

This inscription, which seems to have been a sort of official document, answering the purpose which would now be fulfilled by a printed specification, describes the construction of a temple, and stipulates particularly that the joints of every block of marble must be polished with a mixture of oil and vermilion. As vermilion, if the word so translated really refers to the pigment now known under that name, has no polishing quality, it has been suggested that the color was used simply to spread over the joints before trying the stones together. If any inequality existed in the surface of either stone, it would be immediately shown, on separating the stones after a momentary contact, by the transfer of color from one to the other; and the protruding portion, thus detected, could then be rubbed down by hand to a uniform plane with the rest of the surface. A powder of red chalk is often used by marble cutters for a similar purpose, and it is quite possible that this may have been the only use of the vermilion paint; but there is some difficulty in accounting on this theory for the mixing of oil with the paint, which, if used dry, would be quite as useful for its supposed purpose, and would be much more easily cleaned off the stone. There is no serious improbability in the supposition that the authors of the inscription may have confounded the true vermilion with the red oxide of iron, or crocus, which is a very efficient polishing agent, and if mixed with oil, and applied to the surface of a piece of marble, would serve admirably, both to show where that surface had been brought to coincide with a test plane, and to reduce the inequalities which might on trial be found to exist.—*Am. Architect.*

Separation of Oil from Iron Chips.

The following facts in regard to lubrication and the reclamation of oil under certain circumstances will be of interest to many iron workers and others. We copy from the *Scientific American*:

After good lubricating oil has once been used, coming in contact with the metals and the oxygen of the atmosphere, it has changed its character so much that it is not proper for use as a lubricant, except in the "running through" for lathe and similar work, in cutting screw threads and lubricating for lathe tools. It cannot be returned to the shafts or to the permanent lubricating cups, and do good service. But this once used oil has its second and third use when separated from its surroundings. Oily chips from the lathe, the milling machine, the screw cutting machine, can be cleaned of their load of oil and the oil be returned for use, unchanged except for its semi-oxidation; the contact of iron or of brass will not, of itself, affect the oil. The exposure in dribbles and drops encourages the oxygen of the atmosphere to combine with the carbon of the oil and so change its quality as to prevent its economic use as a lubricant for permanent employment, while it does not impair its value for temporary purposes. For these purposes it does not matter that the oil has partially returned to its base as an acid; its use in running through a screw machine or a lathe is so short that no injury can result. But if once used and exposed oil is fed to shafts and to engine cylinders, the acid from the oxygenized oil will surely make trouble. The proper method of feeding lubricating oil is that of an atmospherically closed reservoir, types of which are largely in use.

But to save oil waste the centrifugal machine is largely in use, and its adaptations

are being extended to comprehend the oily debris of many various manufactures. A recent examination of this contrivance, at an establishment that works steel, iron and brass with oil in streams, shows that the centrifugal machine saves the oil so completely that the resultant turning and drilling chips may be handled without serious soiling of the hands, and the filtered oil appears to be almost as limpid as before using. This appearance is, however, deceptive, for the oil contains chemically, if not suspended mechanically, a large amount of the oxides of iron, steel, brass and bronze, with which it had been intimately associated, rendering it unfit for purely lubricating purposes. But the method of the centrifugal machine is a reasonable and useful one.

TEMPERING STEEL.—In tempering steel, water-mixed with ice gives the best results. One may even insert some small tools to advantage in a lump of ice, as jewelers and watch-makers do when they temper them in sealing wax. Often oil is used, and is preferable to water because it is easily evaporated. Damascus blades, it is well known, are tempered in a strong current of cold air passing through a narrow chink, a temper more uniform than with water being thus obtained. But of all means for this purpose it is believed the most efficacious is metallic liquid, and mercury being the only one known, and always a good conductor of heat, as well as the best of liquid conductors, it has come to be regarded an unequalled bath for the tempering of very sharp steel tools. A very sharp steel, to which in forging it a convenient form was given and which was afterward tempered in mercury, might be equal, it would seem, to cutting through almost any substance.

A POINT IN RESETTING LIGHT TIRES.—A correspondent of *Blacksmith and Wheelwright* says: For the benefit of your readers I will give my way of resetting light tires. I mean those that are bolted on. In the summer time tires are apt to become loose, and the wheel will not wear well when this is the case. My plan is this: I take out the bolts, mark the tire and felly, and drive the felly from under the tire till it falls off. I then get some press paper, such as is used in woolen mills, cut it in strips the width of the felly, and tack it on with small tacks till the wheel and tire measure the same in circumference, or till the wheel is a trifle the largest. I then heat the tire to a black heat, drop it on and let it cool off. If it bursts I sprinkle it a little with water. I put the bolts in the old holes. I never make new ones. This job can be done very nicely, and the result is much better than if the tire was cut and welded or upset. The paper I use is hard and about one-thirty-second of an inch thick.

THE STRENGTH OF BEAMS.—Recent experiments show that spruce beams, loaded to one-half to two-thirds their breaking strain, finally break after a long and steady deflection, which continually increases until the final rupture occurs. If substantiated by further experiments, this fact will go far toward explaining the frequent falling of mill and ware-house floors, under loads supposed by the builders to be perfectly safe. The floors of all such buildings should be sufficiently strong to carry at least five times the weight that can, by any possibility, be put on them, and at least five times as strong as the ordinary load. Where there is running machinery in the building, which is likely to produce jar or tremble, these figures must be exceeded, as the effect of a continuous jar and strain combined is very destructive to the building in which they are found.

THE CARE OF BELLOWS.—"How many bellows have been and are spoiled from negligence in cold weather? They should be oiled two or three times a year to soften the leather, and when not in use (over night), they should be hung up by a chain. But how many smiths or helpers hang them up at night, or when not in use during the day? How many never oil the bellows at all, and leave it lying flat over night? Then on a cold winter's morning, on starting the fire, they give the pole a jerk, and crack, crack goes the leather, and then you will likely hear some strong language about the good-for-nothing leather, and what a poor bellows it is. Clean and oil your bellows before the cold weather comes on."—*The Smithy and Forge.*

AMERICAN EXPORT OF LOCOMOTIVES.—A London journal notes as a fact of special interest to English manufacturers that no less than 151 of the 557 locomotives which were turned out at the Baldwin Works, Philadelphia, during 1883, were exported. Mexico, Brazil, the Argentine Republic, Australia, Cuba, the West Indies, Central America, the Sandwich Islands and Peru, are named as the countries which have been supplied with railway engines from the Philadelphia shops, and from most of these quarters, in future, English manufacturers must expect to deal with American competition.

A NEW ROTARY ENGINE.—Albert H. Gleason, of Wabash, Indiana, has invented and patented a light running and almost noiseless rotary engine. It has a skeleton piston of minimum weight, and its lever power is preserved at a maximum. The engine has but two slides, each with an independent action. Its inlet and exhaust ports are close together, enabling the pressure of a given amount of steam to be utilized for a greater length than can be done in rotary engines where the inlet and exhaust ports are at a greater distance apart.

SCIENTIFIC PROGRESS.

The Northern Polar Sea.

What the Explorers are After.

The recent loss of the *Jeannette* and most of her crew, and the starting of the relief party for Greeley, which has just sailed, is attracting an unusual degree of interest toward circum-polar explorations. The greater the danger, and the more disaster is reported, seems only to increase, in like proportions, the application of new adventurers in this frigid and dangerous field of exploration.

Arctic travelers are all united in an opinion, says an English writer, that birds have told us of regions beyond the frozen seas of the North, where, from some cause or other, the climate is milder, and the ocean or soil more generous. This has been held by many navigators, and each succeeding explorer has confirmed the wonderful story. When Kane, in his small brig penetrated, under unusually favorable circumstances, to the eightieth degree of latitude, he dispatched Mr. Merton with the sledges to reconnoiter, and that able man found, after many battles with the ice, that at the eighty-second degree the icebergs and iceflows over which he had been traveling became weaker, the surface rotten, and the snowdrifts softer, until the dogs, terror stricken, refused to advance, and with much trouble and danger they made their escape to the coast. Mr. Merton then reflected that a great black line he had seen was open water far away to the North, and the unwonted appearance of wild fowl, which had been strangers along the dreary ice packs to the south, convinced him of the accuracy of his belief.

But the aquatic birds were here in thousands, and they seemed to be more numerous in the distant, mysterious north. The Brent geese, the eider and the king duck were so closely packed together that an Esquimaux who accompanied the little expedition killed two with a single rifle ball.

Here we find a curious clew that the birds have given us to the great mystery of the North Pole. From where this was seen to the North Pole is about 450 nautical miles and it may be that milder climates, shut out by mountains of ice ranges, hide what would fill us with wonder. Brent geese, which seem to have prevailed in vast throngs, and may also be known by their wedge-shaped flights, live on marine plants and molluscs. They are not often seen inland, unless flying from one estuary to another, and their presence in these high latitudes is a sure indication of an open sea with feeding grounds, quite unknown further south, on the dreary ice regions that have so long baffled explorers.

Saturn and His Rings.

Numerous have been the theories to account for the singular accompaniment of rings which attend the planet Saturn. To those astronomers who were first enabled to observe this peculiar phenomena it appeared as a single ring, and Maupertuis thought that it was a comet's tail, cut off by the attraction of the planet as it passed, and compelled to circle round it thenceforth and forever. Buffon thought the ring was the equatorial region of the planet, which had been thrown off and left revolving while the globe to which it had belonged contracted to its present size. Other theories also went upon the assumption that the rings are solid. "But if they are solid," asks *Knowledge*, "how is it that they exhibit traces of varying division and reunion, and what are we to think of certain mottled or dusky stripes concentric with the rings, which stripes appearing to indicate that the ring where they occur is semi-transparent, also are not permanent?"

Then, in regard to important physical changes which appear to be going in those rings, *Knowledge* again asks: "What are we to think of the growth within the last seventy years of the transparent dark ring, which does not, as even air would, refract the image of that which is seen through it, and that is becoming more opaque every year? Then, again, how is it that the immense width of the rings has been steadily increasing by the approach of their inner edge to the body of the planet? The bright ring, once 23,000 miles wide, was 5,000 miles wider in Herschel's time, and has now a width of 28,300 on a surface of more than 12,000,000,000 of square miles, while the thickness is only a hundred miles or less.

"In 1857," continues that same journal, "Mr. J. Clerk Maxwell obtained the Adams prize of the University of Cambridge for an essay upon Saturn's rings, which showed that if they were solid there would be necessary to stability an appearance altogether different from that of the actual system. But if not solid, are they fluid? Are they a great isolated ocean poised in the Saturnian mid-air? If there were such an ocean, it is shown that it would be exposed to influences forming waves that would be broken up into fluid satellites.

"But possibly the rings are formed of flights of disconnected satellites, so small and so closely packed that, at the immense distance to which Saturn is removed, they appear to form a continuous mass, while the dark inner mass may have been recently formed of satellites drawn by disturbing attractions or collisions out of the bright outer ring, and so thinly scattered that they give to us only a sense of darkness

without obscuring, and of course without retracting the surface before which they spin."

This appears to be the more rational solution of the problem, and to the excessive bulging of Saturn's equator, which determines the line of superior attraction on that planet. The physical changes which appear to be going on within the rings of Saturn and those upon the body itself of Jupiter are just now the great attractions for astronomers, and appear to be giving us something of an insight into the great problem of world building.

HYDROGEN BY ELECTROLYSIS.—Of all possible methods for the production of hydrogen that of the decomposition of acidulated water by dynamo-electric machines would appear, on the face of it, to be the most extravagant. Yet the question has often been put to the editor of *La Nature*; and in a recent issue the process is explained, and its practicability denied once for all. Supposing a perfect dynamo—that is to say, a machine capable of converting all the work of a motor into electrical energy; and also a perfect voltmeter, having no resistance and using all the current in producing electrolysis of the water. Under these theoretically perfect conditions, a horse power developed by a steam engine will in an hour decompose exactly 166 grammes of water, and set at liberty 18.5 grammes of hydrogen, measuring 296 liters, or 7.27 cubic feet. Supposing that practically the chemical action really utilized by the voltmeter represents 70 per cent of the total energy, it follows that a horse power can only produce 13 grammes, or 146 liters, of hydrogen per hour. The production of a cubic meter of hydrogen per hour would therefore require the total energy of about 7 horse power. Thus the production of 1,000 cubic feet of pure hydrogen by this method would be effected by the expenditure of nearly 200 horse power for an hour; and the probable cost of the process may be left to the reader's imagination.

EARTHQUAKES AND THE CHANGE OF POSITION IN THE EARTH'S AXIS.—At the last meeting of the Geographical Society of this city, Vice President Stevens read an interesting paper on the movement of the poles of rotation, or the change of position in the earth's axis, considered as the cause of earthquakes and the recent great convulsions of nature in Italy, Java and Alaska. The various causes which may be supposed to produce this change of position in the earth's axis of several degrees were considered, and their relative importance discussed. Chief among these causes was mentioned the deposit of immense bodies of sediment, as by the rivers of Thibet, in Central Asia. The disputed question of the solidity or fluidity of the interior of the earth was also considered in its bearings upon the subject. The conclusion was that the problem presented was one difficult of solution, but the time might come when it would be so clearly demonstrated that the wonder would be why the matter had been thought so obscure.

PROFESSOR HUGHES ON MAGNETISM.—In his recent paper to the Royal Society, Professor Hughes dealt with the discovery he has made of the presence, in the interior of a magnet, of waves of opposite magnetic polarity, which balance each other when there is neutrality. In a magnet the polarity at the poles is of one name across the bar, but when the iron is neutral the poles run N S N S..... across the bar. He also deduces the practical results that very thin magnets have greater residual magnetism than thick ones; thick ones have more magnetic inertia, and take longer to magnetize. Bundles of wires are better than solid cores, because they take a higher degree of magnetization, owing to surface exposure; and this is not proportionately counteracted by their higher residual magnetism. Professor Hughes is also of opinion that all matter, and even ether, has inherent magnetic polarity and a saturation point. The curve of saturation for the atmosphere is the same in character as that of iron.

PERSISTENCY OF MICROSCOPIC LIFE.—Among the collections stored in the museum of the Academy of Sciences of this city is a large jar of water taken several years ago from Mono lake. As is generally quite well known, the waters of this lake possess certain chemical properties that not only destroy every form of animal life but even dissolves the bodies and bones, if suffered to remain submerged within it for any considerable length of time. Yet within this jar of water now in the rooms of the Academy may be seen certain microscopic forms of bacteria living and multiplying profusely. This is all the more remarkable from the fact that the water has been reduced fully one-third by evaporation, and of course the destructive elements therein are increased in power by the same proportion.

ELECTRICITY IN THUNDER STORMS.—Physicists have lately been trying to determine by experiment whether the electricity of thunder storms is generated by the evaporation of water or by the condensation of vapor. Freeman and Blake have each obtained results which indicate that no electricity is produced by the evaporation of pure water. S. Kalischer has since made some investigations with delicate apparatus, which have failed to show that condensation or the formation of hail is a source of atmospheric electricity.

EXPERIMENTS MADE WITH GASES UPON INSECTS proved the Colorado beetle hardest of all. It took prussic acid vapor to kill it outright, and was paralyzed in illuminating gas.

TABLE OF CONTENTS.

EDITORIALS.—American Blast Furnaces; Handling Safety Lamps; Cobalt and Nickel; The Warren Drilling Machine, 333. Passing Events; Coal; Low Price of Copper; Quartz; British Mines; The Mining Bureau, 336. Idaho Mines; Smelting; Mixture; An Unjust Law; Art Exhibition; Industrial Progress, 337.
ILLUSTRATIONS.—Warren's Balanced Spindle Radial Drilling Machine, 333. The Sawtooth Mining Region, Utah, 337.
CORRESPONDENCE.—Stoppage of Gold Mining, 334.
MECHANICAL PROGRESS.—Grecian Stone Cutting; Separation of Oil from Iron Chips; Tempering Steel; A Point in Rectifying Light Pipes; The Strength of Beams; The Care of Belows; American Export of Locomotives; A New Rotary Engine, 335.
SCIENTIFIC PROGRESS.—The Northern Polar Sea; Saturn and His Rings; Hydrogen by Electrolysis; Earthquakes and the Change of Position in the Earth's Axis; Professor Hughes on Magnetism; Persistence of Microscopic Life; Electricity in Thunder Storms, 335.
ENGINEERING NOTES.—A New Propeller for Steamers; The Eads Ship Railway; A Novel Piece of Engineering Work; A Japanese Engineer; A Singular Occurrence, 339.
USEFUL INFORMATION.—Electricity in Tanning; Another "New" Explosive; Spinning and Weaving Glass; Bes. Form for Chimneys; A Foundry Heat; Glass Floors, 339.
GOOD HEALTH.—Something About the Teeth and Mastication; The Growth of Brain Power; Overwork; Cure of Elephantiasis by Electricity; The Malignant Plant; Canadian Indian Medicines, 339.
MISCELLANEOUS.—Metallurgy of Nickel; Placer Prospects; Political Malaria, 334. Concentrating Works in Idaho; On Rock Drills—No. 4, 338.
MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 340-41.
MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 344.

Business Announcements

Machinery and Supplies.—Parke & Lacy, S. F.
Chemical Laboratory.—Thomas Price, S. F.
Black Sands.—Almarin B. Paul, S. F.
Optical Goods.—C. Muller, S. F.
Home School.—Miss L. A. Field, Oakland, Cal.
Mica Brokers.—Richard Baker & Co., London, Eng.

Passing Events.

The week appears to have been one of financial disasters in the East, many failures having occurred. They appear to affect more particularly the speculating portion of the community however. It has little effect on this coast where we are every day increasing our number of producers, while the other class is happily lessening in numbers.

Tombstone, Arizona, which had a sensation on the wages question last week, now has another on a bank suspension, causing great consternation among the citizens.

Aside from what we give in our usual mining summary, there is little to report from the mines. Work is now going on steadily all over the coast. The prospectors are pursuing their calling on the mountains and hillsides, and a prosperous season is foreshadowed.

The metropolis was in holiday attire on Wednesday, when the Odd Fellows of this State laid the corner stone of their new temple with appropriate ceremonies.

A more hopeful financial feeling prevails in Mexico. The merchants offer the Government a loan of \$2,000,000, on condition the stamp tax be repealed, and it probably will be done.

The Germania Company sent six car loads of white lead to market last week, aggregating 128,813 pounds. This shows that the Utah product is gaining favor in the market.

Coal.

The annual receipts of coal at San Francisco are constantly increasing. The port is the discharging point for large foreign shipments, and is the distributing point also for the Oregon, Washington and British Columbia coal mining companies. As our manufacturing establishments increase in number and size, which they are doing, our necessities for coal are greater. They are being met, however, by the opening and more complete development of the coast coal mines. In the PRESS of April 5th we gave the total yield of Pacific coast coals from 1860, and now append a table showing the annual receipts of coal in San Francisco from 1860 to 1884 from all sources:

1860.....	77,635	1872.....	434,462
1861.....	116,245	1873.....	454,557
1862.....	130,545	1874.....	531,949
1863.....	135,550	1875.....	538,208
1864.....	167,295	1876.....	648,380
1865.....	150,141	1877.....	576,763
1866.....	192,605	1878.....	626,733
1867.....	248,925	1879.....	618,519
1868.....	282,023	1880.....	654,118
1869.....	328,073	1881.....	899,630
1870.....	320,494	1882.....	932,896
1871.....	315,197	1883.....	899,301

Some of our coast mines have increased their product within the past few years, while others have decreased. The Mount Diablo mines in 1882 yielded 113,255 tons, while in 1883 they only yielded 76,162 tons. The Carbon Hill mine, on the other hand, yielded 64,745 tons in 1882 and 140,135 in 1883. From Seattle we received 150,000 tons in 1882 and 139,600 tons in 1883. Bellingham bay used to send us quantities, but does so no longer.

Our foreign coal comes mainly from British Columbia, Great Britain and Australia. British Columbia shipped here 157,762 tons in 1882 and 128,503 in 1883. From Australia we received 158,901 tons in 1882 and 174,143 tons in 1883. The English-Welsh coal receipts here in 1883 were 131,355 tons, and Scotch 21,942 tons. Of Cumberland and Anthracite (Eastern) coal we got 39,856 tons in 1882 and 43,861 tons in 1883. From Renton, Coos Bay and South Prairie our receipts last year were 43,600 tons.

Considerable coal from British Columbia is now being sent direct to Wilmington, the seaport of Los Angeles, from whence it is distributed by rail to the southward. In San Francisco we received the following amounts of coal in April: Carbon Hill mines, 11,250 tons; Renton, 2,250 tons; Seattle, 14,173; making a total of 27,693 tons from the Puget Sound mines. From the Coos Bay (Oregon) mines, 2,422 tons. Of Eastern coal we received 491 tons of Anthracite and 3,100 tons of Cumberland—3,591 tons in all. British Columbia sent us 14,730 tons, of which 820 tons came from East Wellington mines, 8,205 from Nanaimo, and 10,705 from Wellington mines. We received 10,181 tons from Australia. European coals amounted to 4,408 tons, of which 2,194 tons came from Glasgow, 900 from Liverpool, and 1,314 tons from Newcastle-on-Tyne. This makes total receipts 68,005 tons for the month.

Low Price of Copper.

The low price of copper has not stimulated consumption though it is likely that the use of the metal will be larger in the future. The development of the many applications of electricity for lighting; the transmission of speed and power, is progressing so rapidly that the copper interests ought to benefit by it. The quantities absorbed for the construction and renewal of machinery and railroad rolling stock are steadily increasing, and brass is just now all the rage for decorative purposes. Notwithstanding all these elements in its favor there is not much prospect of a permanent rise in this country independent of a simultaneous upward movement abroad. The principal reason of the view is that we are heavy exporters of raw material. So long as the price of copper here is near the parity of copper in London, argentiferous material will seek that market. Favored by lower prices of labor and fuel and working with prices which permits close work, one firm of Swansea smelters can outbid our own refiners. The lower price obtained for copper allowed is more than balanced by the lower cost of working and higher prices paid for silver. The bulk of the Montana matte goes to Swansea. The furnace material would seek a market in this country should any important rise take place here when there was none in England. How long American metallurgical skill will allow the movement it is hard to say.

Quartz.

The crystals of quartz occur in very many forms. Among the crystalline varieties the rock crystal is colorless and transparent. It occurs in fine crystals in most mining districts, but is rarely abundant. The luster of the finest specimens is rather adamantine than vitreous and approaches that of the diamond. The "California diamond" is a familiar example. They may, however, be readily distinguished from real diamonds by their difference of crystalline form and their inferior hardness and specific gravity. Amethyst is a purple or violet crystalline variety which occurs in many localities. Citrine or false topaz is a yellow variety which sometimes occurs in fine crystals. It may be distinguished from the real topaz by the difference of crystalline form, amount of cleavage and inferior hardness.

Ferruginous quartz is reddish brown rather than yellow and often nearly opaque. It is ordinary quartz much colored with oxide of iron of which it occasionally contains as much as five per cent.

Cairngorn or smoky quartz also occurs in crystals. Morion is a black crystallized quartz which occurs in Scotland and in many of the Cornish mines. Siderite or sapphire quartz is of a rich indigo-blue color, and occurs in impure limestone at Golling or Salzburg. Rose quartz in some localities is quite abundant. Milky quartz is nearly opaque, and is the color of milk, sometimes crystalline, but oftener massive. It occurs in many mines, usually in small quantities. Cotterite is a variety from Ireland, possessing brilliant pearly lustre. Sugary quartz is a granular and somewhat friable and massive variety. Floatstone is a cellular variety. Fibrous quartz or cross-course spar is made up of a multitude of imperfect prisms, pressed confusedly against each other side by side.

The crypto-crystalline or amorphous varieties are several.

Chalcedony is milkwhite, yellow, brown or pale lavender blue. Flint appears to be a variety of chalcedony, having the same hardness, specific gravity and chemical composition, etc., but it differs in some respects. Carnelian is a beautiful reddish-brown variety, much used for personal ornaments. Agate is a complex stone composed of chalcedony, jasper and sometimes ordinary quartz. The chief varieties of agate are onyx, which is composed of alternate bands and sardonyx, which includes reddish or yellowish bands. Plasma is dark green and nearly opaque. Heliotrope or bloodstone is composed of green plasma with red jasper. Chrysoprase is apple green; the color appears to be due to oxide of nickel. Prase is dull green and massive.

Jasper is an opaque massive variety colored by oxide of iron or other foreign substances. It is sometimes banded of different colors when it is called ribbon jasper. Basanite or Lydian stone is a dark variety of jasper. Many other varieties of quartz have been distinguished by special names, many of them more or less local in their character. Sagenitic quartz is simply quartz which incloses other minerals or needles crossing each other, such as rutile, tourmaline and the like. Cats-eye quartz is opalescent from the presence of their fibers of asbestos. Aventurine quartz contains flakes or spangles of mica, chlorite, hematite or other foliated minerals. Elhydros is a term which has been used for quartz (and other) crystals containing inclosed fluids. Quartz rock, the different kinds of sandstone, the buhrstone and many other siliceous substances are rather rocks than minerals.

COLLINS MINERALOGY.—Bancroft & Co. have received the second volume of the "General Principles of Mineralogy," by J. H. Collins, which is intended to accompany and supplement the first volume, published in 1878. Like that, it is written for the use of "practical working miners, quarrymen and field geologists," as well as of the students of science classes. The work is little more than a dictionary of minerals, but the author has made it as complete as possible by including notices of all the minerals described. Many of the notices are brief. The work is illustrated, and is in a condensed form which is practically useful. The chemical arrangement has been adopted, which differs very little from that formerly in use in the British Museum, and is identical with that of Dana's "system," so far as the primary classes are concerned.

British Mines.

For two thousand years diligent explorations have been made in the mining fields of Great Britain, and these fields have supplied metallurgical industries with the native material required for their smelting operations. The drain upon the mineral veins has been constant and excessive. It has been repeatedly urged that the rate at which this exhaustion has been progressing has not received the attention which it deserves. Indeed, there has not hitherto been any comprehensive examination of the subject, though it is true that a Royal Commission was appointed in 1866 "to enquire as to the quantity of coal consumed in various branches of manufacture," and to determine the probable duration of our fossil fuel. The mineral resources of the United Kingdom have been far in advance of those of any country in the world. The annual value of the metalliferous ores and earthy minerals raised has approached to eight million pounds sterling, the result of the difficult and dangerous labors of more than 50,000 miners, directed by a large staff of educated engineers and experienced agents.

Mr. Robert Hunt, Keeper of the Mining Records, formerly Secretary to the Royal Cornwall Polytechnic Society, and Professor of Experimental Science in the Royal School of Mines, also, notably, the editor of Ure's "Dictionary of Arts, Manufactures and Mines," etc., has just published a work on British mining, which is a treatise on the history, discovery, practical development and future prospects of metalliferous mines in the United Kingdom.

Mr. Hunt estimates the weight of tin got in that country from 500 B. C. to 1880 at 3,000,000 tons. There is promise, he thinks, of the production of tin in large quantities at increased depths. Respecting copper, he supposes it improbable that the native mines can be expected to prove profitable for some time to come. The produce of the lead mines has steadily decreased, and the silver found in the lead diminished. The inspectors' returns show that the production of the ores of zinc, until recently, has been small. In 1882 the quantity was 16,130 tons, and of blende 32,533 tons. Respecting iron ore, Mr. Hunt says that they have been exhausting their deposits for many years at an enormous rate, producing annually upwards of 8,000,000 tons of pig iron, importing also from foreign sources 2,450,000 tons of ore. The pig iron manufacturers consume considerably more than 20,000,000 tons of ore annually. In concluding his notice of the iron ores of the United Kingdom not in the coal measures, the total production is given in the year 1882 at 12,852,824 tons. The argillaceous ores from the coal measures in 1882 were 11,505,447 tons, the actual quantity of ore used in our blast furnaces being in that year 26,808,069 tons.

The Mining Bureau.

The term of State Mineralogist Henry G. Hanks expired on Thursday of this week. In order to ensure his reappointment the following petition has been prepared and signed:

To His Excellency, George Stoneman, Governor:—We, the undersigned citizens of the State of California, recognizing the fitness of Henry G. Hanks for the position which he now holds, viz.: State Mineralogist, and duly appreciating the success which the Mining Bureau has achieved under his management, respectfully request and urge your Excellency to re-appoint him when his term of office expires: Louis Francoin, J. D. Coughlin, E. E. Eyre, J. S. Enos, C. H. Livingston, C. H. Burton, Wm. A. Piper, Thos. B. Bishop, J. P. Hoge, Wm. Blanding, Aug. J. Bowie, Jr., R. H. Sinton, Geo. Cadwalader, S. Heydenfeldt, Wm. T. Coleman, Louis T. Haggin, J. L. Flood, E. P. Peckham, Lloyd Tevis, L. L. Bullock, H. A. Cobb, J. B. Haggin, Henry L. Davis, Wm. M. Pierson, Geo. T. Marye, Jr., Martin Mangels, C. P. Robinson, S. Heydenfeldt, Jr., Almarin B. Paul, Joseph M. Nongues, W. C. Hendricks, M. J. Kelly, John R. Jarboe, John S. Ilager, W. A. Selkirk, John Rosenfeld, W. S. Keyes, S. L. Jones, Wm. F. Herrin, Wm. Craig, J. H. Crossman, Hall McAllister, W. W. Kellogg, Wm. D. English, Harry I. Thornton, W. W. Foote, Geo. R. B. Hayes, Henry Schwartz, Cou. O'Connor, Jas. V. Coleman, P. J. Murphy, Wm. P. Frost, A. A. Andrews, David P. Levy, T. I. Bergin, George Hearst, C. R. Greathouse, Martin Kelly, Robert Y. Hayne, W. H. Hoberg.

The Secretary of the Chamber of Commerce has been notified by the Secretary of the Harbor Commissioners, that the complaint of the Chamber of Commerce against the dumpings of the dredges into the harbor will receive the early attention of the Commissioners.

Idaho Mines.

Sawtooth District.

Sawtooth District, Idaho, comprises the mining section situated upon the extreme headwaters of the Salmon river, and derives its name from the precipitous craggy peaks (like the teeth of a saw) of the range of mountains bearing the same name. The geological formation of the country is of a very fine feldspathic granite. The veins are in a granitic rock, well defined, and classed as true fissures, having massive breadth and with long-continued outcrops showing their course on the surface. The district has shown its veins to be strong and permanent and the ore to hold out. The silver is principally in the form of rich sulphides. The district is divided into and known as Lake, Beaver and Smiley gulches or canyons, and in each flow respectively creeks of the same names, which are tributaries of the Salmon river. Mr. W. A. Brodhead contributed to the last report of the Director of the U. S. Mint considerable information about this region, and we condense from his statements some details about the mines. The accompanying map will show the location of the creeks, etc.

In Lake canyon the Atlanta mine shows a large, strong vein from four to six feet in width. Adjoining the Atlanta on the east are the Summits No. 1 and No. 2, which are doubtless extensions of the former lode. The Mono, Baxter, Wire Silver, Comstock, Comet and Silver Bow are upon the same belt of mineral as the Lucky Boy and Scotia, and all show flattering prospects. East of Lake gulch is Beaver gulch, in which the town of Sawtooth is situated. It is the oldest camp in the district, and the business center for the mines of Beaver gulch. The Pilgrim is one of the best developed mines. The ore of this mine is principally sulphurets and ruby silver, and the whole ledge is pay rock. Large quantities of the ore average from 3,000 to 5,000 ounces per ton, while the average value of ore is 100 ounces.

The Bidwell and Beaver Extension mines run parallel with the Pilgrim mine, about half a mile north of it; they are owned by a New York corporation. The Sawtooth Company's group of mines are in close proximity to the Bidwell and Beaver Extension mines. The Silver King mine is a "blind vein." It required a vast amount of patient work to find it, but when struck the owners were richly rewarded for their patience and perseverance. Fifteen tons of ore from the top yielded \$500 per ton. The various companies and individuals owning mines here are working and developing for their own satisfaction, confident that it will in the end amply repay them. Another season will be a very prosperous and profitable one for the owners of the Beaver canyon mines.

Nine miles southwesterly from Beaver canyon are the important mines of Smiley canyon. The principal mining camp and supply point for the mines of this vicinity is Vienna, situated about six miles from the mouth of the gulch. The Nellie group consists of five very important claims, owned and operated by a New York company. They are the Nellie, Nellie Extension, Hudson, Champion and Sawtooth. The best developed claim is the Nellie. The others of the group are only prospects, having but a limited amount of work done upon them. The Mountain King is opened by two tunnels, one above the other, with about 100 feet vertical depth between them. The Solace mine has been considerably explored. Thirty tons from this mine were sold, realizing \$10,000. The Vienna is one of the best developed mines in Smiley canyon, and is steadily producing very high-grade ore. The Lion is located northwesterly from and parallel with the Vienna, and has perhaps the largest and richest outcrop of any mine in that immediate vicinity. The Emma is the oldest location in the gulch, and as it is the same vein as the Solace, will, with the same amount of development, make an equally good showing. There are many other mining locations in Smiley canyon worthy of note. A 20-stamp quartz mill has been erected by the Vienna Consolidated Mining Company.

An Unjust Law.

The Postoffice Department of the Government of The United States is, in most respects, so conducted as to be of the greatest convenience to the public in the matter of prompt carriage and delivery and small cost. In some few things, however, there is room for improvement. A case in point may be cited in our own experience. The publishers of this paper are publishers of a journal called the PACIFIC STATES WATCHMAN, which is devoted to the interests of the large and growing Order of United Workmen. The WATCHMAN is in every respect a first-class, semi-monthly newspaper. It is well illustrated, and great care is given by a special editor to its contents. Over 5,000 copies are printed per issue, and 2,000 copies

difference in the mail rates forcibly. There is no reason whatever that there should be this difference. If the Government loses nothing one way it loses nothing the other. The subscribers of one class of publications should have equal rights as those of the other class. It is hoped that on mature consideration the authorities will see fit to change what is very evidently an unjust law.

Smelting Mixture.

The manner in which smelting mixtures are made is not the same in all works, nor is the system of feeding and charging the furnaces the same. In some smelting works the weight of the fuel is stationary, that of the charge or quantity of smelting mixture corresponding to

or charge, as it is also called, is, of course, to mix a large number of tons of ore with iron ore and limestone, or whatever the flux may be, and then weigh out the charges to the feeder. But wherever there is a variety of ores of different character, which may vary in moisture, size and other conditions, an immediate mixture with the fluxes will hardly give a homogeneous material which will make itself felt in the slag. In this case it is better to weigh each component part of a charge or a half charge separately into a wheelbarrow or car and dump it at or into the furnace. A furnace of the above dimensions will take seventy charges per twelve hours, and will require eight men to serve it.

Art Exhibits.

Among the many meritorious paintings to be seen at the spring exhibition of the San Francisco Art Association are several examples of portraiture by S. W. Shaw, which are in the best style of that well known artist. That gentleman has for many years enjoyed a reputation, not by any means local, for his skill in delineating countenances, and portraying on the canvas peculiarities of expression which none but a true artist, with experienced hand, is able to bring out. This ability is one which is plainly evidenced in those portraits which Mr. Shaw has on exhibition. The writer happens to know two of the subjects very well indeed and can testify to the truthfulness of the artist's touch. The picture of Prof. George Davidson, President of the California Academy of Sciences will strike any one intimately knowing that gentleman as an excellent one. The expression is perfect and there can be no mistaking the fact that the artist has caught the Professor's face just as it is. The portrait of C. W. M. Smith, is perfectly true to life. That of Judge Locke, of Oroville, is also a very effective one. The white hair and beard set off an intelligent face, and gave the artist an opportunity to delineate a striking picture, while the likeness is preserved. A smaller portrait by Mr. Shaw, is that of a lady in a modest hat and sealskin cloak. There is a look of warmth and comfort in the picture which attracts one. The head is smaller than the other portraits mentioned.

The tone, color and treatment would make this picture noticeable anywhere. In none of these pictures is there any straining for effect. There are no accessories such as shrubbery, draperies or surroundings of any kind. The artist has sensibly relied on his skill in portraiture alone to make his picture, and in each instance has he succeeded. The flesh tints are natural, and all the coloring subdued so that none stands so prominent as to arrest the eye or detract from the general effect. Mr. Shaw is not only a skillful, but a careful painter, and, having a pride in his work, lets none go from his hands that does not do him justice. He recently completed two portraits of A. T. Dewey and his wife, which have been much admired by their friends for their truthful delineation and artistic finish. In speaking thus positively of the merits of Mr. Shaw's work we feel that we are only giving credit where it is richly merited, and should say no less personally to any reader or friend desiring our opinion in this direction.

THE STATISTICIAN.—McCarty's Annual Statistician recently issued for the current year is a very useful book indeed. This publication was commenced in 1874, and has been improved and added to each year. It contains 624 pages, aggregating 100,000 facts, over 25,000 of which are new to the present number. In the United States 50 different productions are quoted to June 30, 1883; the important events occupy 3 pages, and bring the U. S. Chronology down to January 18, 1884. The new data, regarding foreign countries, occupies about 75 pages, 18 of which are foreign cities with their populations; 6 pages on Japan, answering general questions regarding that country; 3 pages on Mexico, regarding its area, population, states, governors, weights and measures and productions; 4 pages on the important events of the Old World for 1883, chronologically arranged, and brought down to January 20, 1884. The productions, armies and navies, finances, weights and measures and religious creeds of the world occupy 6 more pages; the balance is of a miscellaneous character, and treats upon nearly every conceivable subject. Weights and measures in general, occupy about 25 new pages, on half as many subjects. All the public land concessions to railroads, canals and wagon-roads ever granted or now pending in the U. S. are tabulated. Last but not least, California is treated to about 20 pages, giving all the principal productions for 1882, and the resources and production of the precious metals for 1883.

THE SAWTOOTH MINING REGION, IDAHO.

of these are circulated right here at home, in this city, to actual subscribers, who pay \$2 a year in advance. On these city papers we are compelled to pay one cent postage each. The other 3,000 the Government takes abroad in this State, Idaho, Oregon, Nevada, Montana, Arizona and elsewhere, from 100 to 6,000 miles, at two cents a pound.

With weekly papers, such as the PACIFIC RURAL PRESS, MINING AND SCIENTIFIC PRESS, etc., there is no such difference for delivery in San Francisco, city and country papers being distributed by carriers at the same rate per pound. Why, then, there should be the discrimination we have mentioned in the case of the semi-monthly journals, it is difficult to see. The difference in the class of readers cannot account for it, nor is there any reasonable explanation to be given. The local officials are of course powerless to act except under instructions, and these rules to which we have referred emanate from the headquarters at Washington.

The publishers of this paper are publishers of both weeklies and semi-monthlies, and they have, therefore, an opportunity of seeing the

the fuel variable; in others the fuel is variable and the charge stationary; in still others the weights of both are variable. Mr. O. H. Hahn, an authority on the subject, thinks this latter plan is an irrational one. He prefers the one where the charge is stationary and the fuel variable, because the furnace is less sensitive to a large quantity of fuel taken off than to changes of charge.

The weights of both fuel and ore charges should be adapted to the area of the furnace at the throat, covering it in thin layers. For a furnace which has an area of 4 feet 8 inches by 8 feet 2 inches at the throat, a good proportion is from 192 to 216 pounds of fuel (half charcoal, half coke) and from 800 to 900 pounds of charge, which is fed into the furnace in half charges through two doors and spread uniformly over the fuel. The furnace is kept filled up to the bottom of the charge-doors. The feeding is done by hand, by means of shovels; but it seems that experiments with automatic feeding apparatus ought to be renewed, as they have not had a fair trial.

The best plan for making a smelting mixture,

STEAM PUMPS.—The Dean Brothers' Steam Pump Works of Indianapolis, Ind., have just furnished the Rust Owens Lumber Co., at Drummond, Wis., a system of water works, including pumping machinery, pipe and hydrants, having a capacity of one million gallons in 24 hours. They have also orders for supplying seven distilleries with the vacuum apparatus required for manufacturing spirits by the Woolner, et al, patent process. These orders require seven large independent vacuum pumps with composition cylinders. The new process is said to be a great advance in distillery. The yield of spirits is increased and the old "mash tubs" abolished.

Concentrating Works in Idaho.

The old Faulk smelter, buildings, crusher, scales, etc., located two miles north of Hailey, have been purchased by Jabez Chase, a well known Wood river miner, for the purpose of being converted into custom concentrating works. Mr. Chase has a process which he finds adaptable to many of the low grade ores of Wood river, but not the red oxides. He will combine a first-class sampling department with the contemplated works, and sample and reduce ores at \$5 per gross ton. This will be of material benefit to a number of Deer creek miners, and especially the Davitt mine, where large quantities of low grade galena ore exist.

The founder of this project assures us that it is his intention to engage extensively in the sampling and concentrating business and to probably locate works at Ketchum before long. Jabez Chase, Superintendent of the Davitt & Silver King M. Co., has 60,000 pounds of machinery belonging to the Bradford concentrator now en route to the Silver King mine, at Sawtooth. The process has been shown by repeated and careful experiment to be the only successful concentrator ever introduced on Wood river, and notwithstanding it is a new model, Mr. Chase is confident of its adaptability to any ores in this region. It saves light and heavy mineral with equal success, and is hence invaluable to the many low grade oxides hereabouts, as well as the galena in quartz. This machinery is now awaiting roads to open here north. It will be placed on the Silver King mine to reduce the sulphurets, etc., in quartz, constituting the second-class ores of that mine. A model of the Bradford machine saves from 95 to 97 per cent of all low grade ores on Wood river. But its practicability, while probable, is yet to be tried. It will, however, undoubtedly be successful on the Sawtooth ores.—*Ketchum Keystone.*

ORE IN SMALL LOTS.—Mine owners who will read the advertisement of the First National Bank of Prescott will see that the concern offers to ship ores and make advances at the rate of 85 per cent of the value of all metals that may be carried by any ore. Mr. F. W. Blake, an assayer of 30 years practice, started this ore shipping business a few years ago. He has shipped for the Dosoris, Silver Belt, Pine Spring and other mining companies, all of whom are satisfied with the way in which he has transacted business for them. He is now a member of the banking firm spoken of and gives this ore shipping business more attention than formerly, for the reason that he has more time to attend to it. Rates of all general smelters within thousands of miles of Prescott are recorded in his office; so, also, figures for transporting ore, by wagon or car. If you bring him a ton, three or four tons of ore, he will have it sampled, make advances, if requested to do so, and send it to the smelter that makes the best bid for the class of ore to which your shipment may belong. For this labor, also that of writing letters to smelting men, railroad men and others, his terms are, we hear, very reasonable. In the absence of general reduction works, owners of mines whose ores will "pay to ship," as the saying goes, can help themselves and other people develop their mines and drive dull care away by mining and shipping ores. Silver ore that will pay 52 ounces to the ton, and which will not cost over \$10 a ton to take it from the mine, will pay a profit. There is, there must be, plenty of richer ore in this vicinity, which ought to be blasted out and sold. Better be mining it out than looking for financial Montezumas to come here and purchase mines.—*Prescott (Arizona) Courier.*

CERRO GORDO.—Last Wednesday a representative of the Inyo Independent visited this famous old town, from which in its palmy days millions of dollars in silver bullion were shipped. The town presents a genuine appearance of one of the old-time "has-beens." Twice visited by the fire-fiend, but few of the stately old business buildings are left standing, and of those that remain only a small number are occupied. The entire business of the town, that in its prime boasted a male population of over 1,500, is now done in one building—store, post-office, saloon, etc. There are probably a dozen or more men at work in and around this town. The Union hoisting works and refinery stand out in bold relief, as monuments of the good old days that are gone, and those who live beneath their shadows point to them with pride and say, "The day is not far distant when we will have use for them again."

THE \$20 RATE ABOLISHED.—The \$20 rate on ores between Hailey and Omaha has again been rescinded, and a uniform rate of \$25 per ton given instead. This rate applies to all classes and grades of ore, base bullion, matte and lead, from Hailey to Salt Lake, San Francisco, Denver, Omaha and Council Bluffs. To Kansas City the rate is \$26, only \$1 more. But as the smelting works there pay \$1 more per ton to sellers than works at any of the other points named above, the rate to that place is practically the same, as far as ore sellers are concerned. This new rate was evidently made at the request of the Philadelphia Smelting Company, and is of decided advantage to that company, but the railway company will undoubtedly lose by the change. The railway is rich, however, and can doubtless afford to favor a local company at the expense of its own stockholders.—*Wood River Times.*

On Rock Drills—No. 4.

[Written for the PRESS by GEO. J. SPECHT, C. E., 418 California St., San Francisco.]

(CONCLUDED FROM LAST WEEK.)

A few objections which are usually made by persons inspecting the Brandt drill for the first time are the following:

First. It is complicated in its construction when compared with the percussion drills.

Second. In deep mines no more water is wanted than there is by nature; the Brandt drill being worked by hydraulic pressure, increases by its discharge the amount of water to be pumped.

Third. In regions poor in water, the Brandt drill seems to be impractical.

We will endeavor to answer these objections.

Ad. 1. The Brandt drill is more complicated than the usual percussion drill. This is, however, not the least objectionable, as the manner the power is applied is perfectly quiet and constant; there are no jars and blows, every part of the machine works quietly and is not exposed to sudden shocks. The fact that in an average of 3 years 6,600 feet of drill-holes have been drilled by one machine without causing any damage to the same—against 350 feet of the percussion drills—is evidence enough to overthrow this objection.

Ad. 2. The amount of water used by one Brandt drill is about 540 gallons per one hour drilling. As the drilling in mines will hardly exceed 10 hours per 24 hours the total amount of water to be raised is 5,400 gallons in 24 hours. Assuming that it costs \$158.18 to raise 1,000,000 gallons per 24 hours 1,000 feet high, we have the cost of 5,400 gallons raised the same distance: \$8.53, which is certainly very little.

With percussion drills the water used for cleansing drill-holes has also to be pumped again, which will amount to about the same as with the Brandt drills, as with the latter less holes are needed for the same face and as the discharge water is used for washing the holes.

Ad. 3. The amount of water used in compressing air for making steam and for cooling the air as well as for washing out the drill-holes, is greater than the amount used for creating the motive power in the Brandt drill, as the useful effect of pumps is greater than that of air-compressors. This shows that the Brandt drill certainly can be used in regions where there is enough water to work percussion drills.

The writer of this paper will gladly furnish any desired information about the subject treated.

The most interesting tunnels upon the Gothard Railroad are the circular ones, of which there are three on the north side and four on the south side of the Gothard tunnel. The lowest on the north side is the Pfaffensprung tunnel, which was necessary to overcome a sudden ascent in the valley of the Reuss. Sketch No. 1 shows the whole development of the line at that point.

The spiral is formed by a compound curve of four different degrees, namely: first, 61, then 33, then 57, and finally again 61, and by the adjoining tangent. The length along the line from the tunnel entrance to the point where the upper line intersects the lower one is 6,986 feet, by which development an elevation of 167.5 feet is gained, the grade being 137.3 feet per mile on the open line and 121.5 feet per mile in the tunnel. The spiral tunnel itself is 4,845 feet long. The geological features of it are as follows, beginning from the lower entrance:

A, 1,469 feet, exceedingly hard and compact granite and eurite, very difficult to blast.

B, 1,605 feet, hard granite gneiss, occasionally stratified.

C, 252 feet, micaceous schist in this strata, with beds of quartz.

D, 1,420 feet, same as B.

E, 99 feet, same as A.

The flow of water from the lower entrance was 1.25 gallons, while the influx at the upper section was 0.44 gallons per second.

The tunnel was worked from both ends with a top-heading, and later with a bottom-heading. The lower heading was worked by machine

drills, while the upper one was driven by hand. The machines employed were at first the so-called Frohlich drill, a percussion drill of European construction. The air-compressors, two in number, were worked by a turbine, which required 527 gallons per second under a head of 31 feet. To obtain this power a dam of solid masonry, 66 feet long, 23 feet high and 10 feet thick, across the River Reuss, and a ditch of 854 feet length and with a cross-section of 21.5 square feet, were required. Four drills and three columns were kept on hand. The wrought iron air-pipe had a diameter of 4 inches, the single length being joined by flanges. The drills are supported by a column pressed by hydraulic pressure against the sides of the tunnel. Three drills, each supported by a separate column, were worked in the face of the heading, which, up to the end of November, 1879, had a cross-section of 86.29 feet, and thereafter varied from 59 to 65 square feet.

Each machine was worked by two men. The drill holes had an initial diameter of 2 inches, and a final diameter of 1½ inches, and a depth of from 2.3 feet to 3.6 feet. Ten to 17 holes were required for one attack, which took from 3½ to 6½ hours for drilling and from 4½ to 6 hours for blasting and removing the debris. The pressure in the compressors was equal to 53 pounds per square inch. Each attack advanced the face from 1 foot to 2.3 feet, according to the nature of the ground. One foot of drift required from 10 to 17 pounds of dynamite No. 1, and from 30 to 88 drills. The repairs on the machines were very numerous, and one or two of them were constantly in the shop.

Toward the end of 1879 it became apparent that the tunnel would not be finished in contract time at that rate of progress (only 364 feet in 105 days), and the contractor decided to employ the then favorably introduced hydraulic rock drills, system Brandt, and also to abandon the top heading and make the bottom heading

PPAFFENSPRUNG TUNNEL.

the advance drift. At the end of January, 1880, all the necessary preparations had been made, and the work with the Brandt drills commenced. On March 15, 1880, the percussion drills were entirely laid aside.

The working pressure on the drill bit varied from 1,050 to 1,450 pounds per square inch. Each machine—two being supported by one column—required 2 men, 8 hours' shift. The interior diameter of the drill rod is 1½ inches, and the exterior one 2 7/16 inches. The bit has four teeth protruding beyond the sides, making a bore-hole of from 2¼ to 2½ inches diameter. Each attack required from 6 to 10 drill holes of a depth from 3 to 5 feet, 3 to 8 hours for drilling, and 3 to 6 hours for blasting and removing the debris. Each attack advanced the heading from 2 feet to 4 feet, according to the rock. One foot of drift required from 6 to 14.5 pounds of Nobel's explosive gelatine, and the sharpening of from 5 to 18 drill-bits.

The connection between the two headings was made at a distance of 3,258 feet from the lower entrance, and a survey showed a deviation of 0.40 feet in alignment, 0.44 feet in length and 0.66 feet in elevation. The total excavation of this tunnel amounted to 92,000 cubic yards.

TABLE 1.—SHOWING DAILY PROGRESS OF ADVANCE DRIFTS IN THE PPAFFENSPRUNG TUNNEL.

	Percussion drills. Hydraulic drill.			
	Smallest daily progress.	Largest daily progress.	Average daily progress.	
	3.23, Dec., 1879 4 92.	4.77, Jan., 1880 8.53.	3.87	July, 1880 6.75
				Dec., 1880 6.75
				Jan., 1881 6.75
	Hand drilling.			
	Lower header.	Upper header.		
	Smallest daily progress.	1.31, July, 1879 1.31.	July, 1879	
	Largest daily progress.	2.61, Dec., 1878 2.85.	Apr., 1879	
	Average daily progress.	2.00	2.15	

While the percussion drills were used the ventilation was procured by the escape of the compressed air, but when the Brandt drills were used, a fan, situated at the mouth of the tunnel, was employed. The air-pipes were of galvanized iron, and had a diameter of 9 inches.

Immediately previous to the connection of the two headings the temperature in the face was 66° F., the outside temperature being 52° F.

Conclusions.

In closing this article I will condense the advantages of the Brandt drill over the common percussion drills, as made apparent by the above details.

The Brandt drill is worked by water under great pressure, varying from 350 to 1,500 pounds. A hollow drill rod and annular drill-bit of hardened steel is constantly and quickly pressed against and into the rock and slowly rotated. The rotation, as well as the pressure, is produced by water; the column bearing the drill is also secured by hydraulic pressure. Even the very hardest rocks are drilled by this machine, without too great a wear on the bits.

The motive power being water, a very high pressure can be used, so that the dimensions of the machine and of the pipes leading the water from the pumps to the drills can be very small. As water is not compressible to any practical extent its use permits a very high efficiency; the water used as a motive power and discharge by the machine is advantageously used to clean and wash the drill-hole, it allows no dust to arise and cools the air wonderfully. The spray of water issuing from the main pipe settles the smoke and fumes of the blast very rapidly and effectually. Even in countries where water is very scarce, the Brandt drill can be used to better advantage than the drills using compressed air or steam, as the water once used by the drills is returned to the reservoir and so is used over and over again. As the power necessary for the Brandt drill is much less than that for the percussion drills, the amount of water consumed by the boiler is less. Rotary drilling, gives a much larger useful effect than percussion drilling; it therefore is very saving in reference to motive power. Small supplies of water, insufficient for any other kind of drilling are sufficient for the Brandt drill. The drill works continuously without blows and shocks; therefore the repairs are very little, nearly none. Holes of large diameter and great depth and in any direction can be bored. The holes are perfectly straight even in the least homogeneous rock; they are perfectly cylindrical for their entire length. The great efficiency of one machine permits to use less numbers of machines and a smaller plant. Therefore the first cost of the plant as well as the cost of working the same is smaller, than that of any other kind of drills.

Shortly repeated, the principal advantages of the Brandt system of drilling are:

- 1.—Less power required and greater percentage of power realized.
- 2.—Small number of repairs necessary.
- 3.—Cheapness of plant.
- 4.—Cheapness of working the same.
- 5.—Absence of dust and noise.
- 6.—Large diameter of bore holes.
- 7.—Effectual ventilation by injection of water under high pressure.

The success of this system is established beyond doubt, as the great many mines and tunnels in Europe have proven. The plants there erected were cheaper than those for percussion drills at the same localities and the work done was also cheaper. The largest progress, 641 feet in one month, ever made anywhere in the world was made by four Brandt drills in July, 1883, in the west header of the Arlberg tunnel, while from eight to nine percussion drills were used in the east header.

It frequently occurs that in deeper mines a natural water pressure can be made available to work these drills directly without requiring any machinery for creating such pressure, which would make the cost of the plant very low. This is successfully done in the mines of Bleiberg and could also be done at the Comstock, New Almaden and other deep mines in the United States.

NOTE.

For this article the following sources have been used, besides private reports and letters: "Der Eisenbahn Unter- und Oberbau, 1879" (a report on the Vienna Exposition, 1879). "Kiedler's Gesell. u. Bohr Maschinen und Luft-compressoren, Maschinen, 1877" (Report on Rock-drills and Compressors in the Philadelphia Exposition, 1876). "Kiedler's Brandt Hydraulische Gesteins Bohr Maschinen, 1877" official reports of the Imperial R. R. Department of Austria. Publications in the papers of the Austrian Society of Architects and Engineers, and the Swiss Journal die Eisenbahn.

ANOTHER important mining sale, says the *Florence Enterprise*, has taken place in the Casa Grande district. It includes the following property: The Captain Luce mine, owned by B. F. Luce; the Copper Elephant, owned by Wm. Dickinson, and the Copper Reef, owned by Jere Fryer and Julius Bauerlen. The consideration for the first named property was \$60,000 and for each of the last two the sum of \$20,000 was paid. The buyer was S. Chamberlain, President of the Casa Grande Copper Company. The properties were recommended and the sale made by Mr. E. O. Kennedy, the well-known mining man of Globe, which is a sufficient guarantee of their value. They are copper properties and lie near the Copperosity.—*Prescott Courier.*

THE TIDE TURNING UP NORTH.—A correspondent of the *Eureka Leader*, writing from Belknap, under date of April 23, says: Since writing you last, another boom has set in, and the people are fairly crazy. The mines are very rich, and work has begun on some of the gulches with magnificent results. On the Dream Gulch, thirty miles from here, they are taking out an average of \$50 a day to the man. The gulch is three miles long. Some very rich quartz claims have been located near here,

ENGINEERING NOTES.

A New Propellor for Steamers.

Joseph Goodrich, of New York, has patented an invention which it is thought by some may revolutionize steam propulsion. The device is certainly very simple and ingenious. The apparatus in question is simply an endless chain of paddles. These paddles, or slats, as they may be called, are fastened in the chain by means of pivots, one on each end, and upon the chain being drawn through the water spread out and present, as a natural consequence, their broadest surface, but are so arranged that on returning to the head of the craft they remain tightly shut, cutting the water edgewise with very little opposition.

Of course one of these chains is attached to either side of the boat, but they are so far under water that their working is not seen, and no wave or commotion is caused. The advantages claimed are first, economy of power and consequently of fuel used; second, the avoidance of the swell often so dangerous to smaller craft in close proximity to a steamer, and third, the safety of the propelling power from the guns of an enemy in time of war. This last advantage is said to be one long sought, and of great importance. The saving of the cumbersome machinery now in use will also be of great importance, and as an illustration of what this saving will be, it is stated that a steamer of the size of the City of Rome, which has machinery weighing seven hundred and fifty tons, can be propelled faster and more steadily under this improved plan, with machinery weighing only one hundred tons.

C. C. Martin, the noted engineer of the Brooklyn Bridge, is interested in the furtherance of this method, and with other New York gentlemen, proposes to fit an apparatus of this kind on one of the largest of the ocean steamers, when an exhibition will be given and a trial trip made.

THE EADS SHIP RAILWAY. Captain Eads gives out that the survey for his projected Tehantepec ship railway is completed. The enterprise, he represents, will be in the hands of a wealthy English syndicate, which will push it to a successful conclusion. The length of the road will be 130 miles, and it is estimated will cost from \$50,000,000 to \$75,000,000. Captain Eads says there is no doubt of his being able to raise the money, and that he will have the road operating within five years. This outlook is doubtless pleasant to Captain Eads, but to Americans generally it gives rise to the reflection that both the railway and the Panama ship canal will be under foreign control, while our Government, which has an immediate and vital interest in both the railway and canal, is a looker-on without voice as to how either shall be managed. It appears as if one of these days there would be a revival and earnest discussion of the Monroe doctrine.

A NOVEL PIECE OF ENGINEERING WORK.—A novel, as well as interesting piece of engineering work has recently been accomplished at Bristol, England, which consisted in the moving of a foot-bridge 134 feet in length, bodily, down the river a considerable distance. The pontoons, by means of which the bridge was floated to its new position, consisted of four 80-ton barges, braced together so as to form one solid structure, sixty-four feet in width, and were placed in position soon after the tide commenced to rise. At six o'clock A. M., the top of the stages, which was twenty-four feet above the water, touched the under part of the bridge, and in a quarter of an hour later both ends rose from their foundations. When the tide had risen four feet the stage and bridge were floated to the new position, when at 8:30 the girders dropped on to their beds.

A JAPANESE ENGINEER.—T. A. Matsvaria, a Japanese educated in this country, is the first man of his nationality who has been chosen to act as a civil officer in the United States. He is the son of a wealthy Japanese nobleman, and came to this country in 1870. After graduating, he determined, decidedly against the wishes of his father and friends, to remain in this country, to acquire some practical experience in his profession, and for some time acted as Assistant Engineer of the Manhattan Elevated Railroad Co., of New York, and afterwards, for three years, Chief Engineer of the Union Pacific Railroad in Wyoming, Idaho and Montana. He has recently been elected as City Engineer of Bradford, Penn.

A NEW STEEL is said to have been produced at Sheffield, England, which is expected to be of incalculable value to the manufacturing and railroad world. It is said to be made "by adding from 7 to 20 per cent of the ordinary ferromanganese of commerce to iron either wholly or to a good extent decarbonized and refined and treated by any of the ordinary processes."

A SINGULAR OCCURRENCE.—A singular accident is reported from the *Derry (Eng.) Standard* to have happened in connection with the insulated electric rail on the Portrush Electric Tramway. A ploughman returning from work on Thursday stood upon the rail to mount his horse, and, on applying his hands to the back of the animal, the brute fell dead, while the man was uninjured as though the current of electricity must have passed through his body to the horse.

USEFUL INFORMATION.

Electricity in Tanning.

Making leather is now essentially the same in principle as it was in the days of the Pharaohs. Improvements have been made in the methods of depilating or removing the hair from hides and skins, and machinery helps to forward the work in both tanning and finishing, but the aid of a vegetable astringent tannic acid is necessary in combination with the gelatine of the hide to make true leather. And this is a long operation, requiring, for sole leather, from four to eight months, and the lighter harness and upper leathers less in proportion. It is now claimed that this long tanning process can be shortened by electricity, and an English patent has been issued with this object. It is well known that the hides being "sweated" for unhairing give off a great deal of ammonia, from the combination of the nitrogen of the gelatinous tissue with hydrogen. This process of decomposition is immediately checked when the hides go into the tan liquors, but the precise chemical reactions which take place in the vats have never been clearly understood. In heavy sole leather it is claimed that in many cases, tannin is deposited by precipitation in the hide cells, besides that which is directly taken up by combination with the gelatine.

A new and improved process has recently been introduced by Mr. L. Gaulard, who has taken out a patent for the same, under the title of "Tanning by Electricity." The skins to be treated by this process, says the *Electrical Review*, are suspended in a solution of tannin contained in a vessel, in the center of the bottom of which is an electrode, another electrode being placed in a conduit, by which this vessel communicates with another vessel. The electric current is then caused to pass in such a manner that the negative pole is in the center of the vessel and the positive pole is in the conduit. Under these conditions, the hydrogen alone acts upon the leather, and causes the rapid destruction of the nitrogenous matter contained therein. After undergoing this treatment for a period of eight days, the liquid in the vessel is removed and replaced by a stronger solution of tannin, making about 20". The current is then reversed, so that the pole in the middle of the vessel becomes the positive pole, and the pole in the conduit the negative pole. The oxygen alone then acts upon the liquid, thereby inducing a rapid oxidation of the tannin, and its precipitation in this condition in the cells formed by the gelatine and fibrine of the hide.

ANOTHER "NEW" EXPLOSIVE.—German ingenuity has produced another derivative from coal tar in the shape of an explosive for mining purposes or firearms. This resultant is a mixture of saltpetre, chlorate of potash and a solid hydrocarbon, the latter being paraffine, asphaltum or pitch. The solid ingredients are powdered and intimately mixed, and the mass is then treated with a liquid volatile hydrocarbon, such as benzine or gasoline, which dissolves the solid hydrocarbon and forms the whole into a plastic body. This cake is then rolled into sheets and hardened by allowing the liquid solvent to evaporate, the product being afterward broken up into grains of any desired size, like ordinary gunpowder. By this method of dissolving the hydrocarbon before or after admixture with the salts, the grains became coated after drying with a waterproof surface of varnish. The new compound is only an explosive when confined in a close space. It possesses the same density as gunpowder, and is very hard.

SPINNING AND WEAVING GLASS.—At Gaudenfel, Germany, the artist and glass-spinner, A. Prengel, of Vienna, has established his glass business, offering carpets, cuffs, collars, veils, etc., made of glass. He not only spins, but also weaves glass before the eyes of the people. The otherwise brittle glass he changes into pliable threads, and uses them for making good warm clothing by introducing certain ingredients, which are his secrets, thereby changing the entire nature of the glass. He makes white, curly glass muffs; also ladies' hats of glass, with glass feathers, which are lighter than real feathers. Wool made of glass, it is said, cannot be distinguished from the genuine article. Glass is a non-conductor, and the time may not be far distant when it will cause a revolution in dress material.

BEST FORM FOR CHIMNEYS.—It is well known that the round form is the best for chimneys in workshops. It facilitates the escape of the smoke and gives less hold for the wind, besides requiring less material for the construction. Round chimneys are, however, difficult to build, and in some places the want of workmen able to make the round kind, has compelled the adoption of square or octagonal forms. To obviate this a European firm makes bricks in the shape of wedges, and corresponding with the radius which the chimney is to have. The Market Street Cable Company adopted the octagonal form in building the chimney for their engine house on Valencia Street.

AN INGENUOUS APPARATUS has been made for Mr. Borden, of Fall River, Mass., which he finds of service in his sleeping rooms. It consists of a small battery connected with an Edison incandescent lamp, which can be lighted up instantly. The circuit wires run from the battery and lamp, located on shelf or table in the

room, to any convenient position near the bed. By a push button, or any other simple method, the circuit may be closed and the room illuminated, the lamp giving about two candle-power. This arrangement of this household convenience was done by Frank W. Harrington, superintendent of the Western Electric Company's factory in Boston, who is now fitting up several for the use of prominent men in New England.

A FOUNDRY HEAT.—A saving of about 80 per cent is made by substituting for the coal-dust and charcoal used with green sand, a careful mixture of one part of tar with twenty parts of green sand. Castings produced from moulds made with such a mixture are smooth and bright, because the tar prevents the metal from adhering to the sand and also the formation of blisters. Such a mixture also adds considerably in the production of large castings, as the tar absorbs the humidity of the sand.

GLASS FLOORS.—In many of the business houses in Paris, and especially in those of which the cellars are used as offices, glass is now being extensively employed instead of boards for flooring. It saves gaslight, and the glass proves, in the long run, full as cheap as, if not cheaper, than the wooden flooring.

METALLIC PAPER is a French invention, and upon it cromolithographs are rendered transparent by a coating and backed with tin foil. The effect is said to be very striking, and the possible applications of the invention are very numerous and useful.

THE ALBUM of the Bank of England in which specimens of counterfeits are preserved has three notes which passed through the Chicago fire. Though they are burnt to a crisp, black ash, the paper is scarcely broken, and the engraving is as clear as new.

GOOD HEALTH.

Something About the Teeth and Mastication.

The following interesting extract from a French periodical we copy from *Health*: "It would be impossible to deny the vast influence which the condition of the teeth exercises upon the general health and many stomach affections. Dyspepsia, for instance, which is so often supposed to spring from remote causes, is, in reality, most frequently one result of swallowing imperfectly masticated food. Reaumur's experiments have long since proved that food cannot be digested unless it is properly broken up. He caused some sheep to swallow tubes full of grass, saturated with saliva, but not chewed. Two days afterward, examination showed that this food had not undergone any digestive change. Spallanzani still more conclusively proved this by causing a sheep to swallow two tubes, the one full of masticated, and the other of whole grass. The chewed grass was digested; the other remained unchanged.

"The state of the teeth not only affects one's bodily health, but also influences character. A bad condition of the teeth, by the prolonged sufferings it occasions, which are aggravated by the most trivial causes, ends by rendering the disposition morose, irritable, and thenceforward inclined to see only the dark side of everything.

"But if it be true that character can be influenced by the state of the teeth, it is also true that the teeth rapidly decay under the influence of overwork? Two English doctors, Messrs. Leithwood and Harlan, believe they have noticed that the teeth of those who devote themselves entirely to study undergo rapid changes, and that a period of rest retards the evil. They then put the further question: Are these occurrences attributable to an over-excited brain, whose excessive stimulation makes it assimilate to itself those phosphatic elements which would otherwise go to nourish the teeth? Or is this decay of the teeth due rather to a low state of health produced by overwork?

"Comparing together numerous facts which have been culled from different isolated observations, Messrs. Leithwood and Harlan find themselves compelled to admit that if the brain be overstimulated by work, the excess of phosphorus which it then consumes can only be gained at the expense of those organs which require this substance for their development, as the bones and the teeth. He advises that the studies of children shall be carefully watched, and so regulated as to be increased or lessened in accordance with the condition of their teeth. He also counsels those young persons who go in for competitive examinations or a university career to exercise the greatest watchfulness over their teeth, if they wish to preserve them."

The Growth of Brain-Power.

The question now arises, says a writer in the *Phrenological Journal*, in speaking of the growth of brain power:—Where in the series of events is there room for any fresh element to come in? Can any man ever be anything other than what some of his ancestors have been before him? And, if not, how is progress or mental improvement possible? That man have, as a matter of fact, risen from a lower to a higher intellectual position is patent. That some races have outstripped other races is equally clear. And that some individual men have surpassed their fellows of the same race and time is also obvious. How

are we to account for these facts without admitting that new elements do at sundry times creep in by chance, in the false and unphilosophical sense of the word? How can we yet advance unless we admit that exceptional children may be born from time to time with brains of exceptional functional value, wholly uncalled by antecedents in any way?

The answer to this question is really one of the most important in the whole history of mankind. For on the solution of the apparent paradox thus propounded depend two or three most fundamental questions. It is by this means alone that we can account, first, for the existence of great races like the Greeks or the Jews. It is by this means alone that we can account, secondly, for genius in individuals. And it is by this means alone that we can account, thirdly, for the possibility of general progress in the race. It is surprising, therefore, that the question has so little engaged the attention of evolutionary psychologists at the present day. There are only two conceivable ways in which any increment of brain power can ever have arisen in any individual. The one is the Darwinian way, by "spontaneous variation," that is to say, by variations due to minute physical circumstances affecting the individual in the germ. The other is the Spencerian way, by functional increment—that is to say, by the effect of increased use and constant exposure to varying circumstances during conscious life. I venture to think that the first way, if we look at clearly in the face, will be seen to be practically unthinkable; and that we have therefore no alternative but to accept the second.

OVERWORK.—A large amount of sentimental rot gets into print about men killing themselves by overwork. In nine out of ten cases of this kind, the true cause of death will be found to be something besides overwork. We all know professional and business men who work harder than they ought, and yet by taking good care of themselves in the way of diet, exercise, etc., manage to enjoy good health and wear a cheerful hearty look. Those who die from "overwork" generally use liquors and tobacco without moderation, keep late hours, and indulge in hazardous speculations outside of their legitimate business. Late hours, liquor and tobacco engender weak nerves and upset the functions of the body, while anxiety over speculative schemes acts on the brain. With these evil agencies working against a man, some slight exposure brings on an attack of illness and the whole body being weakened, gives way in a very short time. The sudden illness and speedy demise baffle medical skill, the stricken family and shocked friends are told that overwork was the cause of death, and the press deplores the tendency of our civilization to kill people by overwork, when the real cause of nine-tenths of these deaths is as outlined above.

CURE OF ELEPHANTIASIS BY ELECTRICITY.—An interesting communication on the treatment and cure of elephantiasis among Arabs by Doctors Monrovo and Silva Arango has been presented to the French Academy of Sciences by M. Gosselin. The cure consists in decomposing the tumid swelling of the limbs, known as elephantiasis, by means of electrolysis, but at the same time the general health of the patient is also treated hydropathically, that is to say, by the cold water cure, sea baths, tincture of iodine, iodide of iron, arsenic, and other tonics. These medicines are intended to renovate the constitution, but are not of themselves sufficient to reduce the tumors. Electropathy, however, applied as soon as possible after the first manifestation, checks, and ultimately cures it. The cure is generally perfect, and takes place at the end of a few days in some cases; but if the elephantiasis is of long standing the cure is also a long process, and must be accompanied by proper medicines. The electrolysis is effected both by continuous and interrupted currents sent through the tumid swelling.

THE MULLEIN PLANT.—A good deal has been written lately about the mullein plant and its efficiency as a cure for consumption. Extracts and decoctions of this plant (*Verbascum thapsus*) were recently exhibited at the Cork Exhibition, but the judges would not pass any verdict, as the chemical and physiological properties have not yet been investigated. It is under the synonym of cow's lungwort, popularly looked upon as a value in diseases of the respiratory organs. In reference to the use of the above, Dr. Quinlan, of Dublin, writes to the *British Medical Journal* that three ounces of the green leaves should be boiled for ten minutes in a pint of new milk. The liquid is then strained, sweetened to taste, and drunk while warm. This dose can be repeated twice or three times a day. This high authority has no doubt of its efficacy as a curative in the earlier, and a palliative in the later stages of pulmonary consumption. Care should be taken to use the leaves of the great mullein, known by its thick, mucilaginous, and woolly leaves.

CANADIAN INDIAN MEDICINES.—The Marquis of Lorne, in his lecture at the Society of Arts on "Canada and its products" speaks of some of the cures effected by Canadian Indian squaws and medicine men. Although many of their medicines are known to medical men, and in spite of the *heros poems*, or incantations, practiced in their application, he believes that there are many herbs which would well repay the examination, and possibly lead to the discovery of valuable remedies.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

POTOSI.—Amador Ledger, May 13: This quartz mine located between Drytown and Plymouth, was taken in hand about nine months ago by a company of nine workmen, who obtained the consent of the owners to work it on their own account, and make what they could out of it, with the understanding, however, that if they should strike anything big, the owners should have the right to immediately resume possession by paying the miners regular wages for the time they had spent on it. After prospecting for seven months, in running a tunnel into the side hill in a northerly direction, a ledge from 12 to 15 ft wide was encountered. The ten-stamp mill was at once started on about six ft of the ledge lying next to the footwall. The entire ledge, it is believed will pay, but the mill is too small to crush the whole of it. They have cleaned up three times, the yield averaging from \$3 to \$3.50 per ton. As the rock is easily extracted, and no hoisting required, the men realize big wages, averaging \$120 per month. It takes 50 inches of water from Purinton's ditch to run the mill.

MISCELLANEOUS.—At the Loyal Lead claim, owned by John Palmer and others, the cleanup last month yielded between \$3,000 and \$4,000—the best run yet made. At the Seaton, they are hoisting water, but not extracting rock. The repairing of the old shaft of the Governor has been finished to the water level. Another rich streak of quartz has been struck in the St. Julian by drifting from the upraise in a northerly direction. The seam is an inch or two wide, but seems to be plentifully charged with gold. The one-stamp mill is running steadily, and a new concentrator, never before tested, is being put in. A cleanup was made at the Iowa mill in Sutter creek, consisting of 20 tons of rich ore from the Iowa mine. The yield was very satisfactory, running up into the hundreds per ton. It took the owners three months to get out this quantity of ore, but it paid them handsomely for their labor.

PLYMOUTH.—Cor. Amador Dispatch, May 8: The mills of the Con. Plymouth Mining Company are kept running and are making their usual output of bullion. The War Eagle claim, one mile west of Plymouth, is being opened by Messrs. Perry, Gordon and Lamb, and is promising exceedingly well. The new claim near Huse bridge is progressing as fast as possible under the circumstances; hoisting apparatus will have to be constructed before they can sink much deeper, and I understand the manager, Mr. Ballard, is now in San Francisco for the purpose of shipping up the necessary machinery. The Tom George claim, two miles north of Plymouth, is showing very rich ore. Mr. George has been on this mine for many years, and while he makes a living by pounding the ore in the mortar, it is a mere hand to mouth business, and Mr. George, in my judgment, is a very foolish man not to let some man or company of men open it up for an interest, or sell it for a reasonable price to some one who could open it up and make it one of the best mines on the Mother Lode. He has ore that will average \$50 per ton.

VOLCANO NEWS.—The mining business is rather slack at present. The Downs mine is not in operation and will not be until R. C. Downs gets back from the Springs. There is strong talk of the Acme mine starting up in a few days; also the Tellurium mine at Pine Grove. Gillick & Phillips are getting very rich rock out of their mine. The Tunnel Co. are working day and night cleaning up the debris caused by the last storm. Bob. Powers is at work in Mohala Flat and is getting very good pay.

Alpine.

WORK COMMENCED.—Monitor Argus, May 10: Work was begun this week on the Polaris mine, owned by T. N. Hanson and R. D. Hawkins, and situated in Mogul mining district. Very rich ore has been struck in this mine, and this summer the owners intend to develop its resources.

Calaveras.

QUARTZ MINES.—Cor. Stockton Independent, May 4: Quartz mining in Calaveras and Tuolumne counties may be said to be only on the threshold of development. In the vicinity of West Point, 15 miles east of Mokelumne Hill, there is a good deal of capital invested in quartz mining, and several mills are in successful operation. A 20-stamp mill is being erected on the Richardson mine, and the Scorpion is stamping out a good deal of precious metal. The Champion is a valuable mine, in which operations are at present temporarily suspended. Preparations are being made to erect on the Tunnel Ridge Hydraulic mine, near Mokelumne Hill, a five-stamp gravel mill. The material in which the gold is found is a sort of cement-gravel requiring stamps to free the metal. In the southern part of Calaveras the prospect is equally encouraging. Extensive gravel mines are being opened up in the immediate vicinity of San Andreas. New mining locations have recently been made in French gulch, Indian creek, Rich gulch, Chili gulch, and likewise a number in the neighborhood of Angels. The Gold Cliff mine in the latter district is regarded with much favor. It is located upon what is known as the "Mother Vein." There are several valuable mines in the vicinity of Angels, the section where James G. Fair operated before he went to Virginia City and became interested in the bonanza silver mines. At Dogtown, Murphys, Douglas Flat, Vallecito and Carson Hill mining is carried on with varying success, and in some of these localities gold-bearing quartz is abundant and rich. As improved appliances for extracting the precious metal from the rock are brought into use, greater confidence in the permanent success of mining pursuits is entertained.

MURPHYS.—Cor. Calaveras Citizen, May 10: Henry P. McNevin was in town last week. The shaft of the Washington mine, of which he is Supt., is now down 213 ft. It is the intention to crosscut for the lode from that depth. A distance of about 75 ft will have to be run before the vein is reached, when it is the opinion of many that a rich body of ore will be disclosed. The shaft is said to be a model of beauty and equal in its substantial timbering to any in this or any other mining region. The Oro Plata five-stamp mill is kept steadily running day

and night, with flattering results. The new tunnel is fast reaching the ore body. The Calaveras which has been stopped for a short time on account of the difficulty of getting wood for the engine, will start up again immediately with renewed energy since the advent of fair weather.

ARASTRA.—Mountain Echo, May 10: The new arastra mill in course of construction on the North End mine, situated about one mile west of this town, and owned by Smyth & Co., will be completed and ready for operation some time this week. John Willey, of Fourth Crossing, lately informed us that he had recently completed an arastra mill, and that he was steadily engaged in crushing ore from his mine which will yield \$40 per ton.

El Dorado.

COSUMNES.—Cor. Mountain Democrat, May 10: Our quiet little camp is beginning to look more cheerful, and we are looking forward to more prosperous times than we have enjoyed for many years. Our mining interests are certainly encouraging, and from the present outlook we may reasonably expect that in the near future we shall hear the rattle of stamps as well as the sound of whistles from quartz mills and hoisting machinery. Mr. Edner is vigorously working his gravel claim, which he has owned for 25 years, and has been working for five years with most favorable results, it having produced many thousands of dollars, and he has rich ground to work for many years to come. Mr. Ball is working his claim one mile west of this place, and is taking out gold to his satisfaction. His claim is worked by drifting part of the season and washing up when water is plenty. There are many other claims in this vicinity and at Indian Diggings that are being worked successfully, but the most important interest of the district is its numerous quartz veins. The Crystal mines, two miles north, has been worked successfully for many years, and Mr. Alexander, the Supt., is running a tunnel to strike the ledge at greater depth, where there is known to be rich ore. Mr. McClellan is opening up the Independence mine with bright prospects. This mine was worked many years ago, and produced a great deal of gold, but for want of proper appliances for saving gold and sulphurets work was suspended, and it has been lying idle for 15 years, but I am glad to know it is now showing some very rich ore. The Whiterock is a parallel vein with the Crystal and Independence and though little developed shows rich ore on the surface and only needs opening up to show a rich mine, and one most favorably situated for water power for mill and hoisting. This, with proper development, will prove to be a mine of great wealth. The Jackson is looking well, and its owners are contemplating the erection of a mill at an early date. An important operation is contemplated to immediately form a consolidation of three mines on the Grizzly Flat ridge—one owned by Mr. Edner of this place, one by Mr. Hanson of New York, and one known as the Middle Fork claim. The consolidation will start a double track tunnel, commencing on the ledge where it crosses the middle fork of the Cosumnes river and run south. This tunnel will be nine hundred ft below the croppings of the ledge on top of the hill, so that when they are in to the center of the hill they will have nine hundred ft of quartz above them. This tunnel will also tap the Missouri, St. Louis, Hazlewood, and other claims on the same ledge. They intend putting in Burleigh drills and driving the tunnel as rapidly as possible, and will commence as soon as they can perfect their organization. At the mouth of the tunnel is a splendid mill site with ample water power for all purposes. The Mount Pleasant is making its usual output of bullion, and is no doubt one of the best mines on the coast.

Mono.

STANDARD CON.—Bodie Free Press, May 8: There has been no perceptible decrease in the flow of surface water, but it is confidently expected that the present warm weather will create a change for the better. South drift No. 1 from south winze No. 2, 385 level, has advanced 20 ft during the week and shows two ft of milling ore. North drift No. 3 from main west crosscut, 385 level, is in 144 ft; progress 18 ft with the vein three ft wide. South drift No. 1 from east crosscut No. 3 has been driven 13 ft; total length 80 ft, where the vein is about two ft wide. Upraise from south drift No. 1, 500 level, has reached a height of 29 ft, where the vein is two and one half ft wide.

BODIE CON.—Bodie Free Press, May 12: Upraise No. 1, 300 level, has reached a height of 190 ft, a gain of 10 ft during the past week. At the top there is about two ft of ledge of low grade. Upraise No. 4 is up 47 ft, a gain of 15 ft, where there is no improvement. Upraise from 770 (Lent) level, has gained 11 ft; total height 48 ft. Here there is a ledge from 2 to 3 ft wide which shows spots of very good ore. At the Bodie Con. mill there was crushed 140 tons of ore. The average assay of the pulp was \$49.52, and of the tailings \$5.89. The most of this ore has been taken from the Vulcan vein, which is not looking so well. The ore is rather low grade. The shipments hereafter will be lighter than heretofore.

STANDARD CON.—Twelve miners were employed in the mine during the week ending May 10th. The flow or surface water has decreased considerably since last report. South drift No. 1 from south winze No. 2, 385 level, has been drained 18 ft. The vein is one and one-half ft wide, of milling ore. South drift No. 3, from main west crosscut, is in 128 ft; progress 14 ft, showing the vein three ft wide. South drift No. 4, from east crosscut No. 2, has been extended 12 ft; total length 92 ft; vein two ft wide. Upraise from south drift No. 1, 500 level, has reached a height of 36 ft, showing the vein two ft wide.

BULWER CON.—Three men were employed during the week. South drift from west crosscut No. 2, 500 level, is in 328 ft; progress 11 ft. The vein is about 15 inches wide.

SYNDICATE.—The mill is running steadily on a good grade of ore.

Nevada.

THE COE MINE.—Nevada Transcript, May 11: E. Hothersall has purchased Mr. Coe's interest in the Coe quartz mine on Little Deer creek, and now he and Messrs. M. L. and D. Marsh own the entire property. They have bought the hoisting and pumping machinery heretofore on the Wide West mine and also some hydraulic pipe from the Sherman Con. Co., and their works will be run by water power.

THE BALTIC MINE.—Nevada Transcript, May 8:

John McBean was down from the Baltic mine yesterday. He says the snow is from two to five ft deep right around the mine, and that until it melts off and the roads get in passable condition he will not try to start the machinery, but will simply get everything in order for doing so when the proper time comes. It will be several weeks before much can be done.

UNDERCURRENTS CARRIED AWAY.—A cave recently occurred at the Wah Yen mine near Moore's Flat filling up the company's shaft and doing other damage. A set of undercurrents in a canyon between Moore's and Orleans Flat, and owned by Messrs. W. D. Long of this city and Wm. Andrews, were carried away by the sliding debris.

MAGENTA MINE.—Grass Valley Union, May 9: The experience of the past Winter, with a rainfall up to the average, has shown the Magenta Mining Company that their pumping machinery is too light to handle the water in the lower levels, and therefore it has been determined to put in a 13-inch engine, which will be put in place as soon as possible. A new hoisting engine will also be put up. These changes will require a suspension of work at the mine from three to four weeks. In the meantime the drain tunnel will be driven to a connection with the main shaft, which will take the flow of surface water, which has been considerable, and will cause a lessening of the water and make it more easily handled by the pumps. On account of the heavy flow of water no work has been done during the winter on the 400 level, but the water has been held at the 300 level, on which and the stopes above work has been carried on continuously. In the drift and stopes of this level there is showing a ledge of good ore from 10 to 18 inches in size, carrying well in good sulphurets and also some free gold, and the general appearance of the mine has never been better. A good lot of rock is accumulating on the dump, and 22 carloads were raised during yesterday. None of the rock will be hauled to the custom mills hereafter, for the reason that arrangements for the erection of an eight-stamp mill are about completed.

Plumas.

A MILL.—Greenville Bulletin, May 7: At a meeting of the Directors of the Lucky S. mine, held on Saturday, it was resolved to put up a mill with as little delay as possible. Men are now at work improving the road for the hauling of machinery. The route selected is over what is known as the old Taylorville grade. From the tunnel in the mine the pay chimney has been opened 218 feet; it extends without change yet, and how much farther is not known. An upraise has also been put through, the depth of which is 95 feet. The ore is of uniform character from top to bottom. Distant 60 feet from the first ledge is another of about equal size and similar character. A crosscut will reach this ledge in a few days. It is expected that both ledges will be found to unite deeper in the mountain. In the face of the tunnel at present the first ledge is two and a half feet wide. The character of the ground and the appearance of the ledges give the strongest indications of permanence. The most experienced mining men who have examined the mine and prospected the ore, are confident that it will mill \$15 per ton. The owners will be well satisfied with much less.

BUTT VALLEY.—Mining is now quite brisk at Butt valley and Dutch Hill. At the former place Caleb Brown is taking out an ounce per day to the man by ground sluicing. The surface of the ground had been worked over once, but Mr. Brown is now working down to the bedrock. In the progress of the work a large ledge of quartz was uncovered; Mr. Brown started a tunnel in the bottom of the ravine and ran about 500 ft where he cut the ledge at right angles. He then ran a drift along the ledge 80 ft. The walls are well defined, and the ledge 18 ft wide where it has been cut through. The ore contains a great deal of red and black sulphurets; it is soft and would be easy to work. At a greater depth the ledge will probably be found harder. No quartz mining has been done at Butt valley. This claim might develop into a valuable property. The rock prospects high.

AT DUTCH HILL the Savercool brothers have a number of men at work, and have leased a great deal of the ground to others, who are all doing well. The brothers have men at work on a tunnel to reach a quartz ledge higher up on the ridge. A great deal of money has been taken out here and at Butt valley, and all below these ledges now found at both places. The prospect is now decidedly favorable for the development of valuable quartz mines in that neighborhood. The Southern Eureka mill starts up to-morrow on ore belonging to McMillan and McDonald. This ore is taken out of a claim adjoining the Southern Eureka ground, and will be milled as a prospect. It is expected to yield a fair return and there is plenty of it.

CONSIGNEE.—Plumas National, May 10: Charley Hanson was in town this week, and tells us that mining matters are booming along up in the Long valley section. The Consigne Company are driving their tunnel ahead slowly but surely, and will get into the right channel after a while. They have spent a large sum of money in prospecting the claim, and deserve to be rewarded with a rich mine. John Jackson is doing lots of work this year, and will make his mine pay rich dividends. Tefft & Co. are going for it, with good chances for a fine season's pay. Several smaller operations are showing some activity, and it is to be hoped that from the many prospects, a number of good mines will result, and a lively camp will show up in that section.

LA PORTE.—Our mines are now running, which gives employment to the idle men and makes the town more quiet, if possible, than usual. It is said that Col. Plum and other distinguished capitalists from Illinois, are to pay us a visit this summer. Col. and Mrs. Plum are to be the guests of Mr. and Mrs. Lillie, while here. Col. Plum is the head of a company that is spending a good deal of money in this vicinity in opening mines. Mr. James Lillie acting as agent, and a good selection did the company make too. Few Eastern companies have been as fortunate in the choice of managers to disburse their funds in this State.

NORTH FORK.—Winter seems to be about gone, and the miners along the river are waking up. The boys at Cariboo are all busy. Jones, Garanson & Co. are piping with a good head of water on Drummond's Point. Big Frank has returned from the States and gone to work running more tunnel than any other man in the State. Emmons and Ware have suspended operations for the present, owing to

high water. Uncle Dave Kirkham is preparing for his annual attack on his river claim. The Savercool Bros. are operating the Dutch Hill mine. They have about 17 men at work, and will have the water through the big ditch in about two weeks. The boys have been prospecting the last two years for quartz at Dutch hill, and it looks now as though they would come to the front with a big mine before long. H. Thompson (Commodore) has discovered and located what he believes to be a valuable mine, on the head of Mosquito creek, and in the same range as the famous Hallsted mine. It is rumored that Baptiste Piazzonia a few days ago refused \$22,000 for his quartz mine, situated near Dutch Hill. Col. R. G. Lansing, President of the Feather River G. M. Co., is on his way from New York, and is expected in a few days at the Savercool mine. He comes for the purpose of starting up the mine. The mine and forty-stamp mill has been idle the past two years for some reason, but will soon be one of the lively camps of the county.

Placer.

FOREST HILL.—Placer Herald, May 10: Every few days heavy machinery is brought through town, intended for the new Washington Mining Co.'s mill. One wheel passed through a few days ago which weighed 8,800 pounds, and this week a large drum weighing 2,100 pounds came in; but the largest wheel is expected shortly to arrive—it will weigh six tons. The whole machinery and buildings of this Company are of a solid and substantial character. The Mayflower Co. are still sinking deeper. Their prospects are looking better. This company deserves great credit for the pluck and energy with which they have prosecuted their works so far. That they may meet with great success, is the earnest wish of all.

San Bernardino.

MINES NEAR OLD WOMEN SPRINGS.—Calico Print, May 11: Messrs. Fossie & Fley own some fine prospects about eight miles north of Old Woman's Springs and about 28 miles south of Newberry station. They recently sold a half interest in one of them, called the Greenhorn, to Mr. Embody, a wealthy capitalist of Los Angeles. Adjoining the Greenhorn is the Blue Jacket claim belonging to Messrs. Fossie & Fley. It is the intention of these gentlemen to co-operate with Mr. Embody to run a combination tunnel through the Greenhorn and Blue Jacket. They have each hired four men to commence work immediately. Mr. Embody and party passed through Daggett last Sunday enroute by rail to Newberry, from whence they would proceed to the above mines by teams. Last Sunday Mr. R. H. Lewis, who has been engaged in mining for a number of years in Nevada county, and at Virginia City and recently employed at the Alford mine, called at our office, and from him we gathered the following information in regard to some mines near Old Woman Springs. He stated that for the last four months he has been prospecting in the vicinity of those springs, and has endured considerable hardships in his efforts to discover mineral bearing ledges. During the stormy weather his prospecting operations were impeded by the snow that fell to a depth of two or three ft several times. His explorations in the locality about eight miles north of Old Woman Springs resulted in the finding of six ledges bearing mineral. Three claims were given the following names by Mr. Lewis: Oasis, May Flower, Eleanor, Maggie, Desert, Prince and Nil Desperandum, all of which have been duly recorded. These claims are about eight miles east of Ord. The Oasis has a 25-foot ledge, samples of ore from the same assaying \$121 in silver and 45 per cent copper. The croppings of the ledge stand up 15 or 20 ft above the surface, and several cuts have been made across it to ascertain character of the rock and the extent of the ledge matter. Mr. Lewis is making arrangements with other parties to have a shaft sunk 150 ft on one of his claims. He considers that he has some good property there, and intends to sell a portion of it in order to get money to develop the remainder. He stated the survey of the Atlantic and Pacific railroad runs within a half a mile of his claims, and that the company has entered into negotiations with Messrs. Fossie & Fley, owners of the Old Woman's Springs to obtain from the springs all the water they may require.

CALICO DISTRICT.—Print, May 10: Messrs. Wm. Robinson, Ed. Lec and John Boge, have leased the west end of the Taggart mine and Messrs. F. M., W. S., and John W. Neel have leased the east end of the mine for six months. The first parties have commenced work and are taking out ore. The second parties are putting up a house and are going to work in a few days. There is a small force of men at work on the Cuba No. 1, the mine recently purchased by Governor Daggett & Co. A boarding and lodging house is being put up for the miners and when it is completed a larger force will be put on. There are five or six men working on the Comet, sinking a shaft and running a tunnel. They are taking out some good ore and will soon take a quantity to the mill. There are four or five men at work on the Thunder, sinking a shaft and taking out good looking ore. There is one man at work on the O. K. Mine. Some three or four tons of ore from this mine were recently milled, yielding about \$150 to the ton. Several different parties have leased the Occidental and are chloriding in various places with encouraging results. Mr. A. Barber has six or seven men employed on the Red Jacket running in a tunnel, who are taking out some fine looking ore. The development of the mine is progressing in excellent shape under the immediate direction of Mr. Robt. Dougherty, the foreman. Mr. Barber has also leased the Veto in Oriental canyon and will soon set a force of men to work on the same.

Sierra.

GOOD CLEAN-UP.—Mountain Messenger, May 10: Jerome York cleaned up his arastra last Wednesday after a 48 days' run, realizing \$800. He estimates that he crushed 72 tons, which would make the yield per ton a trifle over \$11. The quartz crushed was all taken from a raise about fifteen ft long, the ledge being from three to seven ft wide. Everything between the walls was crushed, no selection of rock being made. He is working along towards a stamp mill, having the timbers for the same pretty much all out, and the iron-work all ready to be taken to the mine. This is proving itself what we have often asserted it to be, one of the most promising quartz ledges in this section. The Sierra Buttles Co.'s flume, near No. 7 tunnel, gave way a few days ago. Damages have been repaired. E. J. Jones, of St. Louis, has contracted to run a

hard rock tunnel, 400 ft in length, for the Lincoln Mining Co., Potosi. Wider plates are being used at the Colombo that, it is believed, will save most if not all the gold. A three-compartment shaft at the Marguerite quartz mine will be put down soon as the mine is drained.

Tuolumne.

STARTED UP.—*Union Democrat*, May 8: The mill at the Golden Gate mine has again started up, and the daily song of its stamps is a cheerful greeting to residents of town, whose earnest desire is for a continuance, and that Mr. Wetmore will soon have the mine and mill running in full blast as in days of yore. At present himself and son are crushing rock they had on the surface.

Trinity.

ENCOURAGING WORK.—*Trinity Journal*, Mr. T. J. Blakemore, of Eastman district, was in town this week and from him we learn that the Blakemores are running two arrastras, and that the rock crushed, pays well and regularly. In the mine they are sinking a shaft from the level on which they have been working, and are running a tunnel in another direction, and both give every indication of extent and permanence. At the end of the tunnel the ledge is 2½ ft in width, and prospects well.

PLENTY OF WATER.—The warm days and nights of the past week have had a marked effect in increasing the supply of water for hydraulic purposes, and miners in Weaver Basin, as well as elsewhere in the county, are making good use of all they have. There is yet a fair depth of snow in the high mountains, and water can be depended upon to keep up much later than last season, which is equivalent to guaranteeing an increased gold production for the current year. Trinity county gravel mines pay regularly and the yield can always be closely estimated by the quantity of gravel washed during a season, and this only limited by the amount of rainfall and resulting water supply.

MAKING GRAVEL FLY.—The mine on Oregon Gulch mountain is being vigorously worked this season; they have six hours water per day for sluicing at the present, and Supt. Lovridge is using it for all it is worth. About twenty-five men are employed in the mine, and good results are confidently anticipated.

PAYING WELL.—We learn that Fred Haas' hydraulic mine at Junction City is yielding splendidly this season. A clean-up of the first ten boxes, after a three weeks' run, yielded about \$7,400 last week, and several partial clean-ups have been made with like encouraging results.

BOIT'S HILL.—We learn that John Yule is doing splendid work in the Buckeye Company's mine at this point, and that prospects are encouraging. The water supply is good now and indications favorable for a long continuance.

NEVADA.

Washoe District.

BEST AND BELCHER.—*Enterprise*, May 10: The west crosscut on the 1200 level was extended a total distance of 125 ft, when work was stopped, for the present, and an east crosscut started just opposite that going west. The east crosscut is now out between 30 and 40 ft, and is passing through a promising formation. A second east crosscut has been started on the line of the Best and Belcher and Con. Virginia, which is out a distance of 15 to 20 ft. On the 2700 level the north drift is out about 82 ft, and is in material that assays \$2 or \$3 a ton.

GOULD AND CURRY.—Work has not yet been resumed in the southeast drift on the 2700 level. It will be remembered that when this drift was out from the joint Best and Belcher station a distance of 25 ft signs of water were seen and the diamond drill was put in. When the drill was out some 40 ft a body of quartz was encountered; also, a flow of hot water of considerable volume. This water is now being allowed to drain out.

UTAH.—Work in the north drift on the 1950 level has been discontinued, and a drift started south on the same level. This south drift is out 45 ft. The face is in porphyry, with seams of clay and some streaks of quartz.

SAVAGE.—Are clearing out the north drift on the 2600 level preparatory to putting in the bulkhead. The work is about completed, and the drain boxes have been carried nearly to the face of the drift where the water comes in.

MEXICAN.—The winze on the 3100 level has been sunk and timbered 10 ft during the week. Its total depth is 53 ft, leaving 47 ft to go to reach the 3200 level. There is no change of formation as yet.

SIERRA NEVADA.—Are pushing forward the northeast drift on the 3100 level. A drill hole is here ahead a distance of 170 ft. It shows the ground to be nearly dry. The face of the drift is at present in vein porphyry.

ALTA.—The diamond drill is still being run west from the face of the main west drift on the 2150 level. The rock is exceedingly hard. Meantime both drifts on the 2150 level are being repaired.

UNION CON.—The only work doing on the 3100 is in west crosscut No. 3, which is out 15 ft. It still continues in vein porphyry. The east crosscuts on this level are slowly draining out.

ANDRES.—Some paying ore continues to be extracted, and the prospecting drifts encounter a good deal of quartz of a promising character.

COMBINATION SHAFT.—Are now sinking below the 2800 level. At a proper depth the Cornish pump will be moved down the distance of another lift.

OPHIR.—Some low grade ore from the fillings of the old drifts on the 250 level, and some prospecting is being done.

CROWN POINT.—The usual amount of ore is being extracted, and the mills on the Carson river are kept busily running to their full capacity.

IMPERIAL.—All going on about as usual in the old upper levels. Some very fair quartz has been found at several points.

YELLOW JACKET.—The old upper levels continue to yield well in the usual character of ore, keeping the river mills at work.

Belmont District.

BELMONT.—*Courier*, May 10: Since last report have made good progress in drift on 200-foot level

south. The ledge in face of drift averages three ft in width, well defined and producing fine chloride and black metal ore. Also progressing well with stopes Nos. 3 and 4. As far as the ledge has been tested, it looks very promising. Will commence repairs on mill in a few days.

Columbus District.

MOUNT DIABLO.—*True Fissure*, May 10: There are no very important developments to record during the past week. The east intermediate from winze No. 5 is now in 21 ft, and the west drift is in 15 ft. Winze No. 6 is now down 77 ft. The south crosscut in the intermediate, between the second and third levels, has reached a length of 96 ft. In the same intermediate, and nearly above winze No. 5, a north crosscut has been driven 33 ft, and the west drift has been advanced 7 ft. It is showing a little ore in the face. The west drift on the first level has been stopped, and a crosscut started north from the end of the same. The incline is now 120 ft below the third level, having been sunk 16 ft during the week.

COLUMBUS CON.—The principal part of the work is now being done on the 150-foot and third levels. A west drift on the 150-foot level continues in ore which assays from \$60 to \$80 per ton. This crosscut is about 35 ft in length, and has been running through this strata of ore for the last 10 ft. The raise from the south crosscut, on the same level, continues in very hard rock, and the progress is slow. It continues to yield some ore from which good average assays are obtained. The work of cleaning out the drifts on the second and third levels is nearly completed. All the ore which is extracted is being stowed away in the mine.

THE TILDEN.—The work of putting the new ladders in the shaft has been completed and the machinery has been put in motion. Everything is now ready to commence prospecting. It has been determined to begin cutting out a station at a point just above the water level, from which the work of development will soon be started.

Eureka District.

LOCAL NOTES.—*Eureka Sentinel*, May 8: Charles McLane is prospecting for ore in one of his mines in the Hamburg belt. The Marguerite mine, Adams Hill, is again looking well and producing considerable ore. Prospectors are taking to the hills, and it will not be long before the camp will be looking prosperous again. Evans & Co. are taking out some nice ore from the Tiger Lily and Little Giant mines, on Coy Hill, which they have leased. The Paul Fry mine, Adams Hill, is looking splendidly, but is the only one out of several in that locality that is making a reputation. Parties leasing the General Lee mine, Adams Hill, shipped some ore to the furnaces last week, and are now getting out another batch. The Home Ticket grade has again been shoveled out, and ten tons of ore were shipped from the mine to the Richmond furnaces yesterday. The lessees of the Reserve and King Lear mines, Adams Hill, have 50 tons of first and second-class ore, and 20 tons of flux ore on the dump ready for shipment. Maurice Hartnett has struck a good thing in the Industry mine, near the line of the Piute. He has driven a drift from the bottom of a shaft in the direction named, and run it five ft into a body of good ore with neither sides, top nor bottom, so far as he has gone. Messrs. Doolin, McMann and Crowley are still at work on their pitch in the Helen Mortimer mine, one of the properties of the Hamburg Company. They have considerable ore on their dump awaiting shipment to the furnaces. This cannot be made until the road up New York canyon is cleared of the snow, which, however, is fast disappearing. For several years past lessees have cajoled the mine, but the parties who now have it under lease have started to work systematically and are in a position to take out ore without having to pack it through a labyrinth of holes. The mine is opened by a tunnel, and from this Messrs. Doolin & Co. have sunk a winze to connect with the ore body. The ore was traced through a series of windings until the present deposit was found. It is on a well-defined fissure, running northwest and southeast, and dipping at an angle of about 80 degrees. The ore averages about five ft between the walls. In one place it has been sunk on to a depth of 32 ft and it has been stowed out for a length of 75 ft. It was reported last week that the ore had nearly pinched. This was true, but it has since then opened out again and looks better than ever.

Esmeralda District.

THE HUMBOLDT MILL.—*Bodie Free Press*, May 10: Governor Blasdel is at Aurora, making arrangements to start the Humboldt mill on Silver Lining ore. McKinlay & Co. have finished their contract on the mine, and have made such a good showing that the Governor has concluded to push things vigorously. It will take but a slight start to make the old camp boom.

Star District.

THE GRIZZLY MINE.—*Silver State*, May 9: J. Phillips and J. C. Harris, two experienced miners, left yesterday for Star district. They are going to work with William Woolcock on the Grizzly mine, which is said to be looking splendidly, and which has produced considerable ore in the last year that worked about \$1,000 to the ton.

Taylor District.

LOOKING WELL.—*Cor. White Pine News*, May 3: Our mines continue to look well and are yielding the usual quantities of ore. The Monitor Company started up their mill on the 25th, and she promises to be a good paying institution for a long time to come. The Argus mines are improving in appearance. The new strike I spoke of in my last proves a very important one. Mr. Underhill likes the appearance of the new find so much that he has put on 8-hour shifts, and intends to prove to the world that Taylor veins go down, and that his company will turn out bullion enough the coming summer to pay for the mill and all expenses.

White Pine District.

ORES.—*Cor. White Pine News*, May 3: Transportation between here and Eberhardt is being carried on solely by man-power in front of sleds. D. B. Clark, the leaching process adept, is to visit us soon again and make further examination of our ores. Messrs. Rockhill and Sterrett are at work upon a renewed contract on the Jennie A and Black Rock mines. The Hon. came in yesterday and reported his experience of the trip as the roughest he had ever made to the alpine summit of White Pine.

ARIZONA.

GALENA.—*Arizona Miner*, May 10: A big strike of a large body of low-grade galena ore has just been made in the Buzzard and Raven, one of the Dosoris group of mines. The ore averages about \$125 to the ton. Colonel Greenwell, who has just returned from the Hassayampa, reports the Dunkirk mine, in that district, as rapidly developing into a very valuable property. The Lawrence mine, Agua Fria district, is destined to some day prove one of the best paying properties in Arizona. During the last winter, Jack Lawler, its owner, has sunk a depth of forty ft, and taken out forty tons of sulphide of copper ore, which goes as high as \$500 in silver. Had Turkey Creek the good fortune to fall into the hands of such men as Fair and Mackey, Northern Arizona would witness a boom that would rival the palmist days of the Comstock. The latest strike reported in the district is a three-foot body of \$300 ore on the first extension of the Pine Spring mine, being the property of Messrs. Powell and Ross. The Pine Spring itself, is said to have never looked better. Native and horn silver rock taken from its 70-foot level goes over \$2,000 to the ton, and plenty of it in sight.

COLORADO.

CLEAR CREEK CO.—In lode No. 6 in the Diamond tunnel, the lessees have, during the past week, encountered a six-inch streak of high-grade ore. Superintendent Fish informs us that work will soon be resumed on the old Maine-Phoenix property. This is one of the best mines in Clear Creek county, and has, in past years, yielded enormous amounts of rich ore. Messrs. Goss & Co. have encountered a fine body of copper and galena ore in the cross-cut run from the main drift of the Crown Prince lode to cut the Colorado State. They will shortly test their ore by mill-run. Mr. A. E. Bonham, the owner of the Boyd lode, East Argentine district, informs the *Miner* that work, which for some time has been suspended on the lode on account of the snow, will be resumed on Monday next. A large force of miners will be put to work and the property extensively developed. There are some 300 sacks of ore now at the mine awaiting shipment. Very encouraging are the reports that come to us from the Baltimore tunnel property. Messrs. Samuel Peterson & Co., who are drifting west from the old Baltimore shaft, have a flattering prospect, and are industriously pushing their drift ahead for the purpose of intersecting the large ore body known to exist. Coster & Co., leasing east of the shaft, have six inches of solid ore. The crevice measures from three to four ft between walls. The ore taken from here mills as follows: First class, 800 ounces; second class, 400 to 500 ounces; third class, 250 ounces silver per ton. It carries gray copper, ruby, galena and zinc. Pope & Co. have leased the ground just west of Peterson's, and are drifting and stoping vigorously. They have five inches of A No. 1 ore. Still farther west, and above this ground, lessees are taking out big pay. The first-class ore ranges from 200 to 300 ounces silver per ton. The famous Terrible is putting out some rich mineral. The Silver Ore shaft is now between 700 and 800 ft in depth. In the drift easterly from the bottom of the shaft is disclosed from 4 to 6 inches of 250 ounce mineral, carrying fine-grained galena, gray copper and some ruby silver. The main shaft is still sinking and has now about reached the distance at which drifting easterly will at once begin. This level will be continued for the purpose of intersecting the large ore body known to exist ahead. It ranges from 8 to 18 inches in width, and mills from 300 to 400 ounces silver per ton.

ANOTHER MILL AT EMPIRE.—Mr. J. B. Terry has leased the Bay State mill at Empire, and will soon have it in readiness to treat custom ores. A new sill has been placed under the batteries, and the mill will no doubt do good work. Mr. Terry thinks he will have the mill running by the tenth of May.

SILVER CREEK MINES.—Mining affairs, in this now famous camp, are taking a "boom" as the work of development progresses. The Moore, Farris & Co. lease on No. 1 lode, Jo Reynolds property, is producing some excellent mineral. The sinking of the shaft goes steadily on, and as depth is gained the quantity and quality of the ore grows better. Last week a fine streak of ruby silver was encountered in the bottom of this shaft. The handsome sum of \$8,565 was taken from this shaft in twenty-seven days. In the lease of Messrs. Lewis & Co. on the Jo Reynolds property, 1,000 ounce ore has been disclosed. The lessees throughout the mine are taking out good pay.

IDAHO.

QUARTZ PROSPECTS. *Cœur d'Alene Eagle*.—As the work of development progresses the quartz interests of the camp assume greater and more prominent and permanent proportions. The Cœur d'Alene country is a network of quartz lodes—a veritable mineral farm. Each day the tireless prospectors bring to light the precious mineral ribs with which nature has seamed this mighty mountain range. On the mother lode no additional prospecting has been done owing to the volume of water in the creek. New timbers have been put in, and as the water subsides, further excavations will be made to uncover the lode and to test its width and depth. It still continues the great attraction of the camp, and its marvellous richness is a standard topic of conversation. The Kate Burnett is developed by a tunnel which taps the ledge at a depth of eighty ft from the surface, exposing a breast of high-grade, free gold bearing quartz, with every indication favorable for the continuation of the lode in strength and depth. The Montana is a lode located near the Kate Burnett, and prospects well in free gold as far as developments have progressed. The New Comstock is regarded by experts as the biggest lode in the camp. Since our last issue an incline has been started to cut through the vein to test its width to the footwall. A cross-cut has been run along the length of the lode, demonstrating that the ledge is as wide, strong and rich at the depth attained as on the surface. Several hundred tons of ore are now in sight, and the ledge is so admirably located for working that one man took out eight tons alone last Monday. The mine is being developed under the auspices of the Homestake Mining company, organized by Jas. McKenzie, the discoverer. The Skookum was discovered last year by J. C. Friend. Later, Messrs. Coy & Hess purchased a half interest, and McClaire, Wade & Co., the Colfax bankers, a fourth interest in the mine. Coy & Hess sold a one-

sixteenth interest April 25 to J. M. Elder for \$1,000, and on Wednesday of this week they transferred a three-sixteenth interest to Sid Benton and others for \$3,000. A portion of the lode traverses Sitton creek. The Skookum is generally regarded as one of the most valuable mining properties in the camp.

DREAM GULCH.—Dream Gulch is still the banner dust producer of the camp. The clean up on Wednesday of last week netted 52½ oz., and last Saturday after a two days run with the new hydraulic, the clean up produced over \$1900. Nine men are employed on the day shift and nine on the night shift. After the first clean up it was predicted by the croakers that the gulch would be "spotted," but the results do not realize the prediction. The owners are now developing the ledge which was uncovered two weeks since, and good gold prospects are obtained from the quartz as far as prospected. Thursday's clean up was sixty ounces. Water has failed so the boys have to stop hydraulic, but they are bound to have water at any cost and commenced to-day the survey for a ditch, and expect to have it completed and a good head of water running in ten days.

MONTANA.

THE LEXINGTON MILL.—*Inter-Mountain*, May 12: It is said that on account of the scarcity of free ore in the Lexington the old mill will soon be closed down, as the tailings will not pay to work separately. The mill is an old land mark, having been built in 1877. It has worked some of the richest rock ever produced in the district, and has turned out over \$2,000,000 in bullion. It cost \$14,770 so—just a dollar and six-bits less than estimated by Judge Dav's before he built it. This shows the Judge to be a close figurer. The structure will probably be leased for custom work, as there is plenty of available free ore in the district.

THE MOULTON.—From Supt. J. K. Clark, this morning, it is learned that in the 300 ft west of the drift of the Moulton, early this week, a ten-inch streak of ore assaying \$360 per ton was struck. This exceedingly rich rock greatly enhances the average ore product of the drift, and as the new strike seems to be enlarging westward, Mr. Clark is quite hopeful that it will ultimately in a very important development. If it does not, there will be no disappointment, as the vein in the 300 is rich and extensive as it is. On the 500 level work continues actively in the face of the west drift where, at a distance of 650 ft from the main crosscut, the winze from the 400 level is expected to connect in a few days. The Moulton produced over \$50,000 during April, the battery assays for the month averaging \$60. The company works 100 men.

NEW MEXICO.

SAN DIEGO DISTRICT.—*Cor. Rio Grande Republican*, May 12: Very few of your readers, I think, have ever heard of a mining district of the above name, and indeed it is a very young camp yet, consisting only of myself and partner; but we think we know a good thing when we see it, and we should not camp here unless we had a prospect that was at least as good as any it is probable we should find in the Organs or Lake Valley. Our camp is at the foot of San Diego mountain, about two miles from Truett station, south of Rincon, on the A. T. & S. F. railroad. We have about seven claims, on two of which, the Clipper and the Norton, work is progressing. The mineral is galena and black sulphurets, and a very fair character of ore. There is plenty of ground for prospecting, and all new-comers will get a hearty welcome.

OREGON.

LOCAL NOTES.—*Jacksonville Times*, May 12: Klippel & Keaton of Poorman's creek, are getting ready to clean up. McKee Bros., who are mining on Forest creek, picked up a \$250 piece last week. Huston & Hosmer of Footh Creek have cleaned up, and considering the opportunity, have done fairly. H. D. Russell of Forest creek has been able to do considerable work during the season with his reservoir. Drifting is going on at A. W. Sturges' claim on Jackass creek, with good results. Several men are employed there. Simmons, Ennis & Co's mining ditch near Waldo, which is a young canal, by the way, is already over four miles long and has several feet of water in it. Two pipes are in full blast at the Sterling mine, and Supt. Ennis expects to have a good supply of water until the end of July, as there is a great deal of snow at the head of the ditch. A. L. Roten returned from the Cœur d'Alene mines last week. He says there is no reason for this great excitement, which seems to have been gotten up in the interest of speculators. Snow is still on the ground and no work of consequence being done. Mr. R. says he did not see \$2.50 worth of gold dust while in the camp.

UTAH.

SOUTHERN NOTES.—*Southern Utah Times*, May 10: In local mining matters there is not much of interest to report. Work progresses as usual upon the old reliable Horn Silver mine, regular shipments have been resumed. The Company has declared its regular quarterly dividend of three per cent, or \$300,000, payable May 15th. The new hoisting works in course of erection upon the H. S. property are being pushed forward. The Lulu or First South Extension H. S. M. Co.'s works are in working order and the shaft is being widened to the dimensions of a double compartment. A force of 15 men is employed in the Rattler mine belonging to the Frisco M. & S. Co. and a 75 foot shaft contract has been let during the week to Messrs. Melville & Short, who will make short work of getting the shaft to a connection point with the winze that has been put down all the way in solid galena ore. Upon the whole the Carbonate outlook is now a very favorable one and Supt. Kirby seems justified in indulging high hopes for the Carbonate Camp. It is said on what the Beaver County Record considers good authority that the iron furnaces will not be erected at Iron City as previously contemplated; but at the more convenient location of Iron Springs. The movement will necessitate the total abandonment of quite a large amount of costly labor laid out at the first named location; but on the other hand the manifest practical advantages to be gained by the prospective change of site, will it is claimed, more than compensate for the loss.

National beat Rand.....	.130 " "

**PATTEN'S
CONCENTRATOR AND AMALGAMATOR COMBINED.**

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

The undersigned is now located at the Iron Works, 217 to 221 Fremont street, where he is building the above machines and prepared to fill orders, and guarantee them to do all that is claimed. Estimates given and orders promptly filled for all kinds of mining machinery.

C. W. PATTEN, 217 Fremont Street, S. F.

DOWNIE**EUCALYPTUS****BOILER SCALE****Preventive and Remover.**

(Patented May 8, 1883.)

MINERS' HORSE WHIM.

ONE HORSE CAN EASILY HOIST OVER 1,000 LBS.
at a depth of 500 feet. The Whim is mainly built of
wrought iron. The hoisting-drum is thrown out of gear
by the lever, while the load is held in place with a brake
by the man tending the bucket. The standard of the
whim is bolted to bed-timbers, thus avoiding all frame-
work. When required, these whims are made in sections
to pack on mules.

F. A. HUNTINGTON, SAW, SHINGLE, AND QUARTZ MILL MACHINERY.

We Call Attention to the Following Testimonials as to the Capacity and Durability of the Centrifugal Roller Quartz Mill:

SAN FRANCISCO, Dec. 27, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—The four-foot Centrifugal Roller Mill, bought of you in August, 1882, for the Whidden Gold Mining Company, of Shingle Springs, has given entire satisfaction, both on our own and on custom work, saving from 85 to 90 per cent of the gold in the mill. In conclusion I will say that we are so well pleased with it that Mr. Whidden and myself are putting one of the same size on the Tohongo gold mine, near Ravenna, in Los Angeles county.

Yours truly, P. VEASEY,
31 California St., S. F.

PINE GOLD GULCH, Nov. 10, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR—In reply to your inquiry concerning the working of your Centrifugal Roller Quartz Mill, I am pleased to say that I run one of them for seven months, doing custom work on different varieties of rock, and that the mill gave satisfaction in every respect, and did all that you claim for it.

Yours truly, BYRON JENNINGS.

GARIBALDI MINE, Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to your inquiry concerning the working of the five feet Centrifugal Roller Quartz Mill, bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

Very truly yours, O. B. SMITH.

32 WASHINGTON AVENUE, |
SAN FRANCISCO, Dec. 29, 1883. |

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—Having run one of your Centrifugal Roller Quartz Mills on sample lots of rock from more than twenty different mines, I must say that in every instance it has given the best of satisfaction in every particular; and I recognize its superiority over any other mill manufactured.

Very truly yours, D. O. MOWRY.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

F. A. HUNTINGTON, 45 Fremont St., San Francisco.

CAPACITY AND DURABILITY GUARANTEED.

SEE SAMPLE LOTS OF ORE WORKED.

SEE WHERE A MACHINE CAN BE SEEN IN OPERATION.

CENTRIFUGAL ROLLER QUARTZ MILL.

The work done by the Centrifugal Roller Quartz Mill, during the past two years, on various mines and different kinds of rock, PROVES ALL THAT IS CLAIMED FOR IT, viz.:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

SONORA, CAL., Dec. 1, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In reply to yours of recent date, inquiring about the Centrifugal Mill which I bought of you, I will say that I have run the mill four months on hard rock; and I take pleasure in adding that the mill has in every way given the best of satisfaction.

Yours truly, J. H. NEALE.

GARIBALDI MINE,
Calaveras Co., Cal., Dec. 17, 1883. |

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In answer to your inquiry concerning the working of the five feet Centrifugal Mill, bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation.

Very truly yours, O. B. SMITH.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—Your Centrifugal Roller Quartz Mill has run on the Whidden Gold Mining Co. property at Shingle Springs, El Dorado Co., Cal., about four months, and it has done good and satisfactory work, a greater proportion of gold remaining in the mill than in the stamp battery.

FRED JONES, Supt.

HILDRETH RANCH, Fresno Co., Cal., |
January 11, 1884. |

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR—In regard to your mill (Centrifugal Roller), I have crushed about 500 tons of rock in the mill, and am glad to say that it has given entire satisfaction, and can recommend it to the public as the most expeditious and least expensive method for crushing and milling ore that I have ever seen.

Truly yours, THOS. HILDRETH.

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

SAN FRANCISCO.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or lift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veinlets of quartz speckled with ore. This mine is 1 1/2 miles northeasterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize excelled by none—yes, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

Iron and Machine Works.

MACBETH'S
—PATENT—
STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting.

On account of their great lightness and the form of the arms, they absorb less power than any other pulley.

They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

ST. LOUIS, Mo., Sept. 23, 1883

Messrs. Adolphus Meier & Co. GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its work. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER-BUSCH BREWING ASS'N.

OFFICE OF Supt. of RYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 24, we respectfully inform you that the three boilers built under your patents under steam since September 25, 1881, at the Alexander Platz Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

(Signed) BRAUCKE.

JET PUMPS.

THE CHEAPEST AND BEST

STEAM PUMP for Lifts from 10 to 70 ft.

FOR IRRIGATING PURPOSES

And all General Work where a Simple
Durable Pump is Required.

NO VALVES! NO PISTON!
NO OIL REQUIRED!

Can be Run by a Child.

EACH PUMP GUARANTEED.

PRICE—One-tenth of an ordinary Steam Pump, same capacity.

Call and See One in Actual Operation.

Edward A. Rix,

Sole Agent.

18 and 20 Fremont Street, San Francisco

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN ONE HUNDRED of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to superintend construction and running of furnaces. Estimates given upon application. Send for circular.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gate Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrounding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid in position, see that Valves are stamped "Jenkins Bros." Number 21.

The Hydraulic Mines.

It is not by any means the case, as many suppose, that all the hydraulic mines in California are closed down. A number of them are at work at points where there is dumping ground where the tailings do not incommode others or where the debris does not go into the main rivers. Some hydraulic miners have purchased large tracts of land on to which they lead and deposit their debris, the water then passing off into the streams. Again, other mines of small importance have not been enjoined, but are continuing work. Engineers Allardt and Basset have made a report to the Supervisors of Yuba and Sutter counties concerning the mines of the Bear river basin. They state in their report that there are thirteen different mines at work using the hydraulic process on the opposite sides of the river in Placer and Nevada counties, and enumerate them as follows: Polar Star, Elmore Hill, Rahlin Bros., Bailey Bros. & Davis and Wm Gray, at Dutch Flat; McCloud, Turner Bros. and Linderman, near Quaker Hill; Liberty Hill, at Liberty Hill; Birdseye Co., two claims, near Red Dog; Nevada Company, at Chalk Bluff; and Jacobs Bros., at Quaker Hill. From the best information obtainable these mines are using 3,400 inches of water each 24 hours, and are tailing into Bear river and its tributaries 12,900 cubic yards of debris per day. The mines of Dutch Flat and vicinity, including the mines of Liberty Hill, are working in much heavier material than at the other places, but it is advised that they, as well as the rest be enjoined. In view of the fact, however, that an injunction would work a great hardship upon individual miners, who depend upon the working of their claims for the support of themselves and families, it is recommended that no injunction be applied for that shall operate before the 15th of June, as "considering the enormous quantity of debris that has been discharged into Bear river during the last fifteen or twenty years, the damage that would result would be, comparatively speaking, quite inconsiderable." The report says in conclusion that the construction of restraining dams was brought to their notice, the miners contending that they could be made effectual and built at a moderate cost in the mountain divisions of the river, but the engineers were only authorized to say that as long as hydraulic mining continued the question of dams could not be entertained; but if hydraulic mining was discontinued, then, the said engineers would be the first to lend their support to remedial measures, provided it be first demonstrated that such measures would be absolutely efficient and permanent for all time to come. Messrs. Allardt and Basset testify to the uniform courtesy which was extended to them by the miners, although the latter were fully apprized of the unwelcome nature of their, the engineers, mission.

Four miners, James Lawrence, Coleman Chapelle, Robert Wallace and Joseph Hays were buried in a mine at Forest Springs, about four miles from Grass Valley, Saturday morning. Their bodies were recovered.

A Sand-Papering Machine.

The engraving on this page illustrates the J. A. Fay & Co.'s No. 3, large, six-roll, double-drum sand-papering machine, with expansive feed rolls and vibrating cylinder. This machine is designed to finish lumber to a perfect surface, for painting and varnishing, and is specially adapted for use in furniture and cabinet shops, agricultural implement, wagon and carriage works, car shops, etc. It is a very substantial machine, and its marked improvements give it great prominence among sand papering ma-

the last drum. The finishing drum is placed so that the discharging rollers carry the lumber from it, thus running through and finishing one board, if desired, without another following.

The roughing drum carries a coarse grade of sand paper, and the finishing drum a finer grade. They may be driven in opposite or the same directions as may be necessary.

The lower frame is hinged at each end to the upper frame, so that by removing a pin either drum can be reached by raising the frame with the screw and worm gear, operated by a hand wheel at the end of the machine. The machine

DOUBLE DRUM SAND-PAPERING MACHINE.

chines. It is arranged to work material twenty-four inches wide by four inches thick and under; has a powerful and continuous feed, and it gives to the lumber a perfect surface by once passing it through the machine.

The feeding mechanism consists of six rollers, in three pairs, driven by a strong train of gearing. The upper feeding rollers, with the pressure rollers over the drum, are lifted together in a perfect plane by the movement of four raising screws, operated by a chain and hand wheel. The lower feeding rollers always remain in perfect line with the drums.

It is supplied with two sand paper drums placed in the body of the machine on which the upper frame rests. The drum at the receiving end of the machine has a vibratory lateral motion for removing lines made by irregularities in the sand paper and preparing the surface of the material for a perfect finish after passing

is supplied with a countershaft having 12x6 tight and loose pulleys, which should make 675 revolutions per minute. H. P. Gregory & Co., of this city, are agents for the Pacific coast.

The last council in the Indian Territory passed or amended the mineral law so that a citizen of the nation can associate with non-citizens in the Cherokee Nation; so there is no barrier now in the way to prevent capitalists investing their money in mining operations in the Indian Territory.

Union miners are leaving Tombstone rapidly. Owners of mines refuse to pay more than \$3 per day and will not employ union men at that rate.

The Russian Government, it is said, has decided upon a large issue of gold coin. Ingots of specie have been issued from abroad,

Curiosities of Ore Shipment.

It seems somewhat curious that people think that ore can be worked better somewhere else than at home. Miners ship ore long distances, paying freights, in the hope of getting higher returns than at the works in the camps where the mines are. Ore is shipped from Mexico, Arizona and elsewhere to California to be worked, and it is also shipped abroad from this State. They have been shipping ore from Calico, San Bernardino county, to Pueblo, Colorado, and now comes one of the owners of the Benson Smelting Works, Arizona, and proposes to have them ship ores to those works for beneficiation. He is going to have a permanent agent in the camp to buy ore to ship it there. Ore comes here from Nevada and is also sent from here. There are big works in Montana, but great quantities of ore are shipped from there to Europe. Idaho and Montana send ore to Utah. Arizona and Mexico send it to California and Colorado. Idaho also sends it to Nebraska. A curious instance of this cross-shipment of ore is that which shows that during the month of April the Denver and Rio Grande Railroad Company carried sixty-one cars of ore, aggregating 1,230,000 pounds, from Utah to Colorado to be smelted. During the same time the road brought sixty-five car loads of Colorado ore, 1,270,000 pounds, for reduction at smelters in Utah. Both Colorado and Utah have earned a reputation for the success of their smelting works, and thousands of tons are now worked there which are mined in other regions. Baltimore, Maryland, works considerable copper ore from this coast. New Jersey and New York do some work on ores mined on this coast, and Chicago will probably do a good deal of this work in the future. The Selby works, in this city, have for many years been engaged in smelting lead and manufacturing a commercial article. The Melrose works, down the bay, have been intermittently carried on. It seems strange that capitalists here have not long since established extensive works somewhere on the shore of San Francisco Bay for the treatment of various kinds of ores. As it is there is no place here where ores can be worked in large quantities by different processes. In this respect San Francisco, and in fact, California, is much behind the times.

THE SAVAGE BULKHEAD.—Work on the bulkhead which is being placed in the north drift on the 2600 level of the Savage is making good progress. It is thought it will be completed in two weeks. The stone are all cut on the surface, fitted into a model representing the bulkhead, and then each block is marked with a number. These blocks will be placed in the bulkhead below just as they were laid in the model on the surface. The bulkhead will have in it a waste-cock through which the water will flow until the mason work is completed, when it will be closed. Below this waste-cock, down near the floor of the drift, will be placed a pressure gauge, like the pressure gauges used on steam boilers, by means of which the exact pressure on the bulkhead can at all times be observed with perfect accuracy.

CORRESPONDENCE.

We admit, unendorsed, opinions of correspondents.—Eds.

A New Nickel Salt.

EDITORS PRESS:—The ordinary nickel zanthate is at first yellow, becoming reddish quickly, and when dried on the water-bath is almost red. It is very soluble in ammonia without heating. In the course of my experiments I have twice accidentally produced from the yellow zanthate, a compound of a beautiful green color, quite different from the green of cobalt zanthate. It is insoluble in cold concentrated ammonia, but is decomposed by boiling in that. On drying with gentle heat, it assumes the color and properties of the yellow zanthate. I believe it is a hydrated zanthate. The conditions under which this new compound is produced are as yet not certainly known to me. It was obtained during the re-solution in dilute ammonia of dried yellow zanthate.

C. H. AARON.

Berea Grit.

The Berea sandstone, Berea grit, Amherst stone, or Ohio stone, as it is variously called, is a characteristic member of the sub-carboniferous rocks of Ohio, found about 300 feet below the Coal Measure rocks, with its outcrop extending from the Ohio river northward through the central part of the State into Huron county, and passing thence easterly, in an undulating line, to near the northeast corner of Trumbull county.

It is ordinarily a rather fine-grained sandstone, with a sharp grit, but differing greatly in its character in different localities. Amherst has furnished from it the best building stone, Berea the best grindstones, but other localities in the region described are capable of furnishing equally good material for both of these uses.

In places the rock is massive, in others it is in regular layers, of a thickness varying from several feet to a few inches. Much of the latter is evenly bedded, making an excellent flagging stone. In some of the quarries, especially in Huron county, these thin strata furnish the finest examples of ripple-marking to be found in the State.

Its exposure in Summit county is confined to the valley of the Cuyahoga river and the bluff bordering it. It appears at the bottom of the valley near the south line of Borton township, and from thence rises in the bluffs to the north line of the county. It is in this county a hard, evenly-bedded, compact rock, varying in color from nearly white to a dark brown, but in places so irregularly colored as to detract somewhat from its value as a building stone.

The quarry most extensively worked is a little south of the village of Peninsula, in Borton township. The upper part has been removed by glacial action, leaving about 40 feet undisturbed, which can be quarried with a slight stripping of earth, while the product is carried by a gravity road to the canal and railroad below.

Some years ago a diligent search was made in the State for a stone especially fitted for the construction of a safe vault, and after thorough tests the white rock from this quarry was selected as the best that could be found. The preference was given to it on account of its strength and bardness, and because of the facility with which blocks of any required size could be obtained. It is largely used for buildings, for abutments of bridges, and other similar purposes. But there is a special use to which it has been applied which is worthy of mention.

Mr. Fred. Shumacher, of Akron, is the founder of the oatmeal industry in this country, and has also been extensively engaged in the work of pearling barley. He found considerable difficulty in obtaining millstones suitable for his work, and after protracted tests of all available material, selected the white variety of this Peninsula stone as the best that he could find. Its great hardness and very sharp grit especially fitted it for this use. A layer, the bottom of which was 3 or 4 feet above the underlying shale, proved to be the best, that which is of strictly first class quality having been yet found only in this quarry. He has used for this purpose about 250 blocks, ranging in diameter from 4 to 5 feet, and in thickness from 14 to 18 inches, and has sold to others about 30 such blocks. These blocks he values at from \$1 to \$2 per cubic foot. In his mills at Akron he is now using 28 runs of these stones, and producing 80,000 barrels of oatmeal and 50,000 barrels of pearl barley per annum. The stones used for pearling barley are placed upright in iron shells revolving slowly in a direction opposite to that of the stone. Mr. Shumacher is now putting the machinery into a new mill, which will increase the annual production of oatmeal to 240,000 barrels, of the value of \$1,500,000.

The success of this industry is largely the result of the peculiar character of a small part of the stone from this quarry. The work was commenced in 1856, and has steadily increased until the present time. Its dependence upon the character of this rock, in the estimation of Mr. Shumacher, is indicated by the fact that he has purchased the entire quarry and is now putting it in shape for a large production of building stone, expecting, as this is removed, to uncover and make available a full supply of that which is especially fitted for milling purposes.

The Extraction of Sulphur.*

Sulphur is found either in superficial deposits, the result of volcanic emanations, constituting the solfatara, or else at a considerable depth underground, associated with calcareous and bituminous marls, gypsum, celestite, etc., forming the sulphur mines, which are the most important sources of this material.

The principal mines are in Sicily and in continental Italy.

The ore is got out with picks, and is transported from the mines on the backs of men. Its extraction is effected by the partial combustion of the sulphur. This causes heat enough to fuse the remaining portion, which then flows into a hollow in the ground, from which it is collected. In Sicily the sulphur is treated in a kiln termed the *calcaroni*. It consists of a wall inclosing an inclined circular area, on which the ore is placed. The heap is covered with a layer of spent material thick enough to keep the combustion from proceeding too rapidly, and spaces are left here and there for the insertion of fagots of wood. The *calcaroni* ready, the fagots are lighted, and the access of air so regulated as to avoid active combustion and too high a temperature. After the operation has been in progress a certain length of time, the operatives begin collecting the sulphur, and continue it until the ore is exhausted. In this operation considerable quantities of sulphur dioxide are produced, and in consequence of the difficulty of regulating the draft, much sulphur is wasted. (Great damage is caused to the surrounding country, and any cultivation of the ground within a certain radius of the burning places is prevented. So great is this nuisance that the Government of Italy forbids "burning the ore," between the 1st of July and the 31st of December.

The *calcaroni* yield but 50 per cent (at most 60 per cent) of the sulphur contained in the ore, the rest serving as the fuel, and thus producing torrents of sulphide dioxide. The imperfections of this process have for a long time given rise to numerous attempts to devise a more rational and less costly method of extracting the sulphur, by the employment of some other kind of fuel. Heated air, steam under pressure, superheated steam and carbon bisulphide to dissolve the sulphur, have in turn been proposed for the purpose of obtaining the greater part of the sulphur without the production of sulphurous acid fumes.

In the first of these methods, a chamber of masonry is filled with the ore, and a current of warm gas, from a hearth fed with wood or coal, is sent into it. This prevents in great measure the production of sulphurous acid, but the action is slow and the mass of ore is irregularly heated. A large amount of fuel is used and the number of hands is increased, so that the economy over the old method is very small.

The use of steam seemed at first sight to offer the best solution of the problem; for its action is very simple and rapid, and the sulphur obtained of good quality. The yield is better than in the *calcaroni* process, and no sulphur dioxide is produced.

But the advantages of this method are counterbalanced in great part by the extra expense of purchasing and maintaining the equipment, as well as furnishing the fuel. The apparatus necessary are the boilers for heating the water tanks to receive the ore, and other accessories. The water available for supplying the boilers is bad, rapidly forming crusts, which increase materially the cost of maintenance. Besides, the proportion of fuel used is considerable, in consequence of the large amount of steam necessary to heat the ore, as well as the loss of heat due to radiation from the uncovered surfaces of boilers, tanks, etc. This process can not be applied in all cases, for the increased yield will not compensate for the greater cost of operating.

The treatment by carbon bisulphide, though very rational *a priori*, presents inconveniences that make its use impracticable. This solvent volatilizes very rapidly, making it difficult and dangerous to work with, besides causing a considerable loss of material.

These difficulties have prevented the various processes from being used to any great extent, so that the old method of the *calcaroni* is the one still generally employed.

In 1805, Thomas proposed immersing the ore in salt solutions heated to a suitable temperature. Balard, in 1867, thought the water from the salt marshes, which is rich in magnesium chloride, might answer. And finally, in 1868, Laperais took out a patent in Italy for the extraction of sulphur by the immersion of its ores in a liquid heated 10 degrees or 20 degrees above its fusing point. By this means, it is separated from the earthy materials associated with it. He used a solution of calcium chloride. The apparatus consisted of a spherical boiler of 2,000-liters capacity, furnished with a stop-cock for drawing off the liquid sulphur, and surmounted by a vertical cylindrical part, into which, with the aid of a pulley, a basket of perforated iron, filled with the ore, can be let down upon a grate.

The apparatus is placed in a furnace and heated directly, while the cylindrical portion is surrounded by the warm gases passing up the chimney. The basket of ore is let down into the solution of chloride of calcium heated to 130 degrees. The sulphur melts, collects in the bottom of the boiler, and is drawn off by the stop-cock and poured into molds. When the ore is exhausted, the basket is raised and immediately immersed in water contained in another boiler

heated in the same furnace. This was used to supply the place of that lost by evaporation in the first.

At that time, chloride of calcium was comparatively dear, so that the patent could not be worked successfully, and was soon abandoned.

Very recently this process has been taken up by MM. de la Tour and Dubreuil, and put into practice by them with success.

Chloride of calcium is now very cheap, in consequence of the rapid development of the soda industry (the ammonia process). It can be put down at the sulphur mines in Sicily at 9 francs per 100 kilos.

The apparatus of MM. de la Tour and Dubreuil consists of two rectangular tanks, holding about two cubic meters each (2 m. by 1.30 m. by .75 m.). The bottom of the tanks is inclined one-tenth. They are placed in the same furnace and heated alternately by the same fire, which is fed with coke, lignite or coal. The ore is placed in one of these tanks, in which is also placed a solution of calcium chloride boiling at 120 degrees. Heat is then applied, the sulphur melts gradually, and is drawn off directly into molds by means of a spigot.

The whole operation lasts about two hours. The end is reached when the sulphur ceases to flow. The calcium chloride solution is then drawn off into the other tank previously charged with ore. Half of the liquid flows through a communicating tube; the rest is received in a vat built in the ground, and is raised by a pump. The gangue is washed to regain the salt which it has absorbed, and this dilute solution is used in filling the tanks as occasion demands. The heat is then directed upon the second tank, and the first is cleared and recharged. There is no interruption in the work, and the heat from the fire is all utilized. The sulphur obtained contains only .1 per cent or .2 per cent of impurity, whereas that obtained from the *calcaroni* contains from 2 per cent to 3 per cent. There is left in the gangue but 4 per cent or 5 per cent of the sulphur originally contained in the fresh ore.

In this treatment certain ores are completely disintegrated, in consequence of the fusion of the sulphur, which is then mixed with earthy matter. MM. de la Tour and Dubreuil, in order to overcome this great inconvenience, were compelled to change completely the plan of their apparatus. The new plan which they adopted is applicable to the treatment of ores of all kinds.

The tanks are built horizontal, and are divided longitudinally through the center by a gutter with inclined sides, which collects the sulphur, and from which it is drawn. On its two sides, iron gratings are built vertically to keep the ore from falling into it. These gratings are made of bars of sheet-iron 2 mm. thick and 25 mm. wide, placed 3 mm. apart. By this new arrangement they can treat ores of all kinds, even the fine powder formed in mining the ore. This powder is very rich, and is known in Sicily as *sterri*. It was formerly left at the mines. This *sterri* is always richer than the average of the mined ore; for in getting the ore out, the rock breaks and divides along the lines of least resistance, which in this case are the veins of sulphur. On account of its friability, the sulphur is reduced partially to dust and forms a large part of the mixture.

At the Tronica mine, in the province of Caltanissetta, in Sicily, the ordinary ore gives 21 per cent of sulphur when treated by the calcium chloride method, while the *sterro* yields 72 per cent. The average yield of the Sicily ore, treated in the *calcaroni*, is from 12 per cent to 13 per cent. In some few cases, it reaches 17 per cent.

On comparative treatment, the same ores yielded from 10 per cent to 12 per cent by the *calcaroni* process, and from 19 per cent to 23 per cent by fusion in chloride of calcium bath.

It has been known for a long time that ores very rich in sulphur acted badly in the *calcaroni*. The combustion is too rapid; and the sulphur, browned and viscous from overheating, is hard to draw off. In order to treat such ores, it is necessary to mix them first with inert material when the yield is not in accordance with the primitive richness of the ore. These rich ores are, on the contrary, treated advantageously in the chloride of calcium bath.

After the treatment of a large amount of *sterri*, MM. de la Tour and Dubreuil estimated the cost of extraction of a ton of sulphur at 12 francs 75c. in the case of a mean yield of 33 per cent of the weight of the ore.

The cost of treatment of one charge (about 1,000 kilos) in their apparatus, is as follows:

	Francs.	C.
35 kilos fuel (coal mixed with lignite) at 30 francs per ton.....	1	5
14 kilos chloride of calcium, 2 per cent carried away by gangue after washing, at 9 francs per 100 kilos.....	1	25
Labor.....	1	25
Unforeseen general expenses, 20 per cent.....	..	70
Total.....	4	25

Thus, in order to obtain a ton of sulphur, three charges must be worked, making the cost of extraction 12 francs 75 centimes per ton.

An operation with *sterri* requires an hour and a quarter for fusion, a quarter of an hour for drawing the sulphur, and an hour and a half for washing the gangue and letting it drain, clearing the tank and putting the movable gratings back in place.

MM. de la Tour and Dubreuil have already introduced a number of their tanks in the sulphur region, principally for working up the *sterri*. There are three at the Tronica mine, in the province of Caltanissetta; two at the Grottarossa mine, in the same province; two at Per-

nice, near Recalmuto, and two at the mine Crocca.

The method just considered presents great advantages over the older methods:

1st. It allows the extraction of the greater part of the sulphur from ores of every kind, at a minimum cost for fuel.

2d. The extraction is effected regularly, protected from atmospheric influences.

3d. Work is carried on throughout the year, as no sulphurous acid fumes are formed.

4th. It permits the treatment of the ores according to the demands of the trade.

The Glendive Gold Discovery.

J. T. Leads, a ranchman in the Red Water country, some sixty miles north of Glendive, Montana, has given the *Times* the following information concerning the new gold discoveries reported in that section a few days ago: "I met two men named Kelley and Collins, from Miles City prospecting down Red Water, on which they found color all the way. I accompanied them to Lone Tree Gulch, a branch of Red Water, which they prospected and found fair pay in every hole. They made ten prospect holes, in one of which at a depth of six feet they struck rock, in which gold was found in quantity. They would go no further, and covering the rock left for supplies, with the understanding that they would say nothing about it. In one pan from the grass roots I saw seven bright colors, three of which were good size, and the miners estimated it worth fifty cents to that pan. These prospect holes could not have been salted and I closely watched their movements, and neither of them had ever seen the gulch before. I am building a house, and in the meantime live in a tent pitched alongside of Adams' house. They slept with me and during my absence Mr. Adams heard them say: 'There's where we'll locate,' meaning the gulch, as they were talking about it at the time. They found some quartz specimens on the trip which looked good."

Lone Tree Gulch is a branch of the Redwater, about twelve miles long, well watered and fed by innumerable springs. It empties into the Red Water about twenty-five miles from its mouth. This is sixty miles from Glendive, which is the nearest point on the railroad.

Mechanics' Institute Fair.

At a meeting of the Board of Trustees of the Mechanics' Institute Fair, it was decided to open the exhibition on August 5th and close it on September 6th.

The following committees for the fair were appointed:

Auditing—C. Waterhouse, A. W. Starbird and B. Jackson.

Building—D. A. MacDonald, C. Hopps and A. W. Starbird.

Circulars and Classifications—B. Jackson, C. F. Bassett and J. Hendy.

Printing—George Spaulding, C. F. Bassett and W. P. Stout.

Power and Machinery—James Spear, J. Hendy and David Kerr.

Rules and Awards—A. Starbird, James Pendergast and G. Spaulding.

Tickets and Awards—W. P. Stout, David Kerr and C. F. Bassett.

Music and Decoration—J. A. Bauer, C. Hopps and A. W. Starbird.

Privileges—David Kerr, C. Hopps and A. W. Starbird.

Location and Police—J. Pendergast, C. Hopps and D. A. MacDonald.

Horticulture—C. Hopps, B. Jackson and G. Spaulding.

Gas and Water—J. A. Hendy, C. Waterhouse and J. Spear.

Special Exhibits—C. F. Bassett, W. P. Stout and Charles Hopps.

IDLE MEN IN THE NORTHWEST.—There are said to be more idle men now in this district, says the *Butte* (Montana) *Inter-Mountain*, than ever before despite the fact that more men are now employed than at any previous time. Hundreds of disappointed *Cueard* Alene stampedeers have come to Butte. Miners are coming from nearly every district in Colorado, Leadville and the camps in Gunnison, Clear Creek, Gilpin and other countries being now on the rapid decline. Mining companies all over the State are discharging men by the hundred. Utah mines are now working smaller forces than ever before, and outside of Alta, Frisco and Park only limited operations are conducted. Silver Reef is dead, Tintic and Dry Canyon ditto, and Bingham is dying. Utah has only two great mines, viz: The Ontario and Horn Silver. In Nevada mining is also at a low ebb, and as in Colorado and Utah the cause is to be found in the low price of lead. Eureka is no longer a hurrah camp, and all the other camps in the State are very dull. As a result of this general depression, miners are flocking to Montana, and particularly to Butte. They cannot all find employment here, and we fear there will be some distress unless the Utah, Colorado and Nevada booms are resurrected. It is said that one company in this district has a hundred applicants a day for work.

A GOOD DEAL of ore is being taken out in Safford district. The Onondago folks alone have shipped 2,500 tons of high-grade ore, and have on hand an immense amount of low-grade that will be worked at the new furnace.

* Translated from the *American Chemical Journal* from a paper by M. Camille Vincent in the *Bulletin de la Société Chimique*.

MECHANICAL PROGRESS.

Observations on Hardening.

Too many of the so-called steel articles sold in the market are either made from steel incapable of being hardened, or are not hardened at all. Good cast steel can be hardened and tempered so as to receive and retain an edge. This is not required of table cutlery generally—only of the carving knife—but it is required of the hand saw and the buck saw, of the spade and the manure fork, of the scissors and the pocket knife. Saw blades (so far as the writer has tried them) are not hardened; they will not retain "set" nor hold edge. They are gunned, as they come from the rolls and the slitting machine, with no pretense at hardening or tempering. But they are stumped "cast steel," and that probably satisfies the public; but there are mechanics who would pay something extra to get good hardened and tempered saw blades, even at a much higher cost than that of the soft plates, the teeth of which can be bent by thumb and finger, and the set of which is removed by sawing through an inch thick spruce board.

A spade is only an enlarged chisel; it should be capable of retaining an edge sufficient to cut through tough turf and deep grass. But most of the "cast steel" spades in the market can be sharpened as readily by drawing the edge cold under the hammer as by the grindstone. The edge never breaks, but batters and bends.

The trouble with almost all the cast steel tools put ready-made on the market is, that they have never been hardened. Cast steel unhardened is as soft as wrought iron uncase-hardened. A cast steel hammer becomes so indented on its face by driving nails during one season in jobbing that it had to be reground and polished. Yet the hammer was of steel capable of being hardened, as was proved by its being subsequently hardened and drawn to temper. It is quite possible that the reason why many of these articles prove to be soft is not that the material is not good, but that they have never been hardened. Brightened steel that has not received a hardening may respond in after heating to several of the tempering colors, and this is probably one reason why common steel articles are not thoroughly hardened.

It is not uncommon to see a forger or temperer heat a piece of cast steel to a very low red—a red that shows only in the shadow—and then brighten and draw the temper to color, when the after-trial proved that the steel had never been hardened. Indeed, the dull red that some smiths use for hardening such tools as cold chisels and other low grade tools is that at which a red annealing may take place—the piece being heated to a dull red and plunged into water.

The first requisite in making a cast steel tool into a working tool is to harden it. After its hardness is proved, then it may be tempered to the condition required. There is no intermediate process of properly tempering between absolute hardening and subsequent drawing.—*Scientific American.*

SHRINKAGE.—There is but very little material that keeps the same size under all circumstances, says E. H. Davies, in the *Architect and Building News*. Metals shrink and expand—some very much more than others—according to change of temperature. Like metals, different woods vary much in shrinkage. But all woods of the same variety will shrink in size, in proportion to the amount of water or sap contained in the wood. One variety of wood may contain four times the quantity of sap, and still not shrink near so much as others. Lumber sawed from trees growing on a hillside, or near the water, or on the south side of a grove, will shrink very irregularly. Some parts will shrink very much more than others, more particularly endways. The same is true with a tree that grows very much out of perpendicular. Suppose a tall tree was growing at an angle of forty-five degrees, the tree itself being perfectly straight, as soon as the tree was cut down it would partially assume the shape of a rainbow. Nearly all lumber shrinks more or less endways. Some lumber will shrink on one side and expand on the other as it is sawed. This is very noticeable in sawing lumber from logs. For instance, the first board sawed from a log may be longer than the log, or vice versa, according to which side the sawing was commenced. It is also very noticeable in ripping up lumber; sometimes when the saw gets well into the board, it begins to pinch, and has to be wedged, but after the saw gets nearly through the cut begins to open. It is doubtful if there is any lumber known that shrinks as much endways as redwood. That wood shrinks on an average one-fourth of an inch in twelve feet; but there are cases when it is four times that amount.

GALVANIZATION OF IRON MECHANICALLY AND MEDICALLY CONSIDERED.—One of the Philadelphia medical inspectors has directed his investigations to medical phenomena involved in the galvanization of iron. In this process, he says, the metal is first heated in a bath containing a strong solution of hydro-chloric acid, then transferred to the molten zinc, which is kept continually charged with dry muriate of ammonia. At each time the ammonia is added to the zinc, the salt (ammonia) is decomposed and the water of crystallization is driven off in dense volumes of steam, carrying with it portions of the acid

elements of the seething mass. The action in the zinc tub is so intense when the ammonia is added, that flames will dart up from the surface to the height of four and five feet. Even if there should be no chemical union of the elements driven off, forming an acid compound, irritant particles would be carried into the atmosphere by the intensity of the ebullition following each addition of ammonia to the zinc. The objectionable feature presented in this case is that, owing to its specific gravity, this pungent vapor is not carried very high into the atmosphere.

THE MANUFACTURE OF CUTLERY.—An invention by which the manufacture of cutlery and like articles is greatly facilitated was lately produced and patented by H. Hallstrom, of Eskilstuna, Sweden. A blank of sheet iron or steel is placed between two dies and hollowed out or concaved, and the concaved part is then punched out of the blank. In the same manner one end of a long blank, which has the length of the knife or fork, is placed between the dies and hollowed or concaved, and is then punched out. The pressed handle blanks consist of a right hand and a left hand blank, so that when the open sides are placed together a hollow handle is formed, one-half of which is made integral with the knife itself. The two handle blanks, after having been placed against each other, are then heated and placed between two dies and subjected to blows by which they are welded together and a hollow handle integral with the knife is formed. After having been welded, the knives and their handles are finished, ground and polished. Light, strong and durable handles can thus be made very easily and rapidly, and they can not become separated from the knife or fork. Handles for screw drivers, chisels, gimlets, draw knives, etc., can also be formed by this method.

AMERICAN BESSEMER CONVERTERS.—The Bessemer converters in England do not approach in productiveness those of the United States, but when it comes to the rail mills, it is difficult to ascertain which is entitled to the cake, the English or the American. The greatest tonnage of rails ever rolled in one week at the Edgar Thomson Steel Works, on one mill, was 4,110 gross tons. This was the week ended March 1st. The best work ever done in one week in England, on a single rail mill, was 4,310 tons of rails, or just 200 tons more than were rolled at the Edgar Thomson Works. This was the week ended February 9th. The mill that did this belongs to Bolekov, Vaughan & Co. Apparently, the English mill did the most work, but doubtless this is only apparently; for as a rule, English rails are much heavier than American rails, and hence the same number of passes through the rolls would give a greater tonnage in the one case than in the other. Unless the average weight of the rails produced by each mill were known, it would be impossible to ascertain which mill did the most work. The number of rails produced would doubtless be a fairer test of capacity than the number of tons.

ARTIFICIAL OBSIDIAN.—A Pittsburgh chemist is said to have rediscovered the lost art of making articles from obsidian, a species of volcanic glass, among them black mirrors which are used in making astronomical instruments. His attention was first directed to the subject in 1879, while on a visit to Pompeii. Here he found a fragment of a statue (an arm) made from obsidian, and its evident kinship to the lava, there so abundant, led him to think it might have been made therefrom. Bringing away with him his trophy and a quantity of lava, he began an investigation and a series of experiments which finally led him to a knowledge, not only of the component elements of obsidian, but also as to how it might be reproduced by artificial means. His first successful "melt" was made in Pittsburgh in the latter part of 1881. He made a number of ornamental articles and several slabs of the new glass went to New York City and set up a small furnace for its manufacture.

IMPROVEMENT IN WELDING BOILER SEAMS.—An inventor in Scotland has patented an apparatus for welding the seams of steam-boilers. For this purpose he employs a modification and extension of the roller flue-welding machine, well known in the United States, and extensively used in railroad shops. The device consists of a hydraulic cylinder and ram, the ram being fitted with two rollers—one to roll along and operate with welding pressure on the joint, and the other to roll along the opposite part of the shell, in combination with external blocks, which confine the shell and prevent its enlargement during the operation. There is no reason why a boiler shell should not be treated like a flue, and the joint welded instead of being riveted. Quite a good many experiments have been made with welding boiler seams, but the results have not encouraged boiler-makers to extend the practice. Perhaps the welds may prove more satisfactory when they are made with a heavy machine designed for the purpose.

THE LEAD BATH FOR HARDENING.—Users of the lead bath for heating for hardening make frequent mistakes in allowing something besides lead to form a portion of the bath, and also in allowing the bath to be kept below its proper temperature. Only pure lead should be used to obtain the full heat for hardening good tool steel. A mixture of lead and tin—a melted mass composed of pewter, type metal, and soft solder—is not a lead bath. The melting and heat holding qualities of metals are not alike.

SCIENTIFIC PROGRESS.

A New Method of Approach.

At an International Polar Conference held in 1879, at Helsingborg, a proposition was discussed and finally determined upon, to establish a series of circum-polar stations at the most practicable positions on the northerly limits of the various countries whose territorial limits enter within the upper limits of the arctic circle. In accordance with this plan some twelve or thirteen stations have been thus established, as follows:

The United States in Lady Franklin Bay, in Smith's Sound, and also at Point Barrow; Denmark at Godthaab; Germany in Cumberland Sound, on the western side of Davis Strait; England at Fort Rae, in the heart of the Hudson's Bay territory, near the Great Slave Lake; Russia at the mouth of the Lena and at Moller's Bay, Nova Zembla; Holland at Dickson's Haven; Norway at Boscop, in the Alten Fjord; Sweden at Spitzbergen; Austria at Jan Mayen Island, famous for its fog and ice. The Finnish Landak equipped a meteorological station at Solaukyla; a branch station was also established in Labrador. France selected a station near Cape Horn, and Germany also ventured into the Antarctic regions by sending a party to one of the islands of South Georgia, in 54 degrees south latitude and about 1,100 miles to the eastward of Cape Horn.

These stations are to forward and assist in every way practical the various special expeditions sent out by different governments; also to send out sledge expeditions at favorable times, and to make local meteorological and other observations. From several of these stations interesting reports have been received. Reports from the Finnish station Solaukyla were rich in scientific material. Experiments on a gigantic scale were made with the aurora borealis, and by an arrangement of batteries and wires along the face and up to the summit of a hill 1,000 feet high, an artificial aurora was produced which differed in neither appearance nor spectroscopic analysis from the natural article. A photograph could not be obtained even with the most sensitive dry plate. The English station at Fort Rae did good work, especially in spectroscopic observations. Good results have been obtained from the Swedish station at Spitzbergen.

The station at point Barrow, on the northern coast of Alaska, was in command of Lieut. P. H. Rae, who, together with his party, spent two years in scientific work. Having completed their building, the meteorological instruments were placed, and hourly observations were begun. The season being much advanced, the members of the expedition devoted much of their time to collecting botanical and zoological specimens. The magnetic work was very trying during the winter, as delicate instruments had to be manipulated and read in temperature as low as 45 degrees below zero. Over 90,000 readings were taken and recorded from December 1, 1881, to August 1, 1882. Meteorological work was done at the same time.

Phosphorescent Light.

In his "Science Notes," in a recent number of the *Gentleman's Magazine*, Prof. W. Mattien Williams says: "My note on this subject last July was preceded by one on the researches of Professor Radziszewski. I learn that he has actually separated the luminous matter of the *Pelagia noctiluca*, one of the multitude of species of marine animals that appear like little lumps of jelly, and produce the phosphorescence of the sea. He evaporated to dryness 180 specimens, and from the dry residue dissolved out by means of ether a peculiar kind of fat, which, mixed with potassa, gives out, when shaken, phosphorescent flashes. This is exactly what happens to the living animal. When quiescent it is not luminous, but if shaken or rubbed it flashes. I have collected and examined a great variety of these animals at different times, the most remarkable occasion being one morning after a magnificent display of marine luminosity in the Mediterranean, a few miles off the shore of Algiers. The surface of the sea was encrusted, I might almost say, with countless millions of small jelly-like creatures, of spherical, ovoid, oblong, dumb bell and other shapes, varying in size from a mustard seed to a pea; a bucketful of water taken over the ship's side appeared like sago broth. They were all internally dotted with a multitude of what I suppose to be germs, that would be liberated on the death and decay of the parent. The practical importance which I attach to the study of the luminosity of these creatures is the fact that they supply light without heat. The costliness of all our present methods of artificial illumination is due to the fact that we waste a largely disproportionate amount of energy in producing heat as well as light. This wastefulness may be illustrated by supposing that we obtain a pound of the phosphorescent fat of the *noctiluca* and divide it into two equal halves, making one-half into candles to burn in the ordinary manner, and using the other half to give out its light by cold phosphorescence. I am not able to give precise figures, but I believe that I am well within the truth in estimating that the candle would dissipate 95 per cent of the potential energy of the fat in the form of heat, giving but 5 per cent of the amount of light that the other half pound would emit as cool phosphorescence. Let us, then, hope that Professor

Radziszewski will continue his researches, and discover the whole secret of both the analysis and synthesis of this fat, and that of the glow-worms, the fireflies, etc. Now that we can supply the confectioner with the flavors of almonds, raspberries, jargonelle pears, nectarines, etc., and imitate the perfumes and the richest colors of nature's sweetest and brightest flowers, all by the chemical manipulation of coal tar, we need not despair of solving the chemical problem of transforming mutton suet, or palm oil, or vaseline, into glowworm, or *noctiluca* fat, to be used for illuminating purposes."

ASTRONOMICAL PROGRESS IN AMERICA.—The visits of foreign astronomers to observatories on American soil have of late years been very frequent, says *Science*; and it is not, perhaps, too much to say that the impressions they have carried away have in the main been of a pleasantly favorable and in some instances of even a surprising character. Occasionally they have made free to express themselves with regard to the somewhat rapid development of, and the future outlook for, their science in this country; but only infrequently have their opinions and criticisms been placed on permanent record. During the latter part of the summer of 1883, Dr. Ralph Copeland, astronomer to the Earl of Crawford and Balenres, and editor of the lately discontinued journal *Copernicus*, passed through the United States, and visited a goodly number of the more active observatories, among them those at Cambridge, Washington, Princeton, Albany and Clinton. His general impressions, as he modestly styles them, are far from uninteresting; and, while there is much that has been suggested before, American astronomy has not yet advanced to a stage where no opportunity offers for advantage from such suggestions.

IS RAINFALL ON THE WESTERN PLAINS INCREASING?—Travelers in the west during the past few years will surely have met the statement that the rainfall of the dry region beyond the Mississippi is increasing. Many western settlers express the basty conclusion that the change is a steadily progressing one, and is due to the cultivation of the ground; and the more venturesome theorists explain the increase as an effect of the better equalization of electric conditions of the atmosphere, as allowed by the laying of iron rails, and the stretching of iron wires across the plains. In regard to the above *Science* remarks: The natural extension of these theories pictures the plains in the near future redeemed from their present unprofitable dryness by persistent occupation. It is well to set these unwarrantable fancies face to face with the matter-of-fact statistics lately published by the signal service; for, whatever the doubtful possibilities of man's power may be, the connection of such small artificial changes with variation of rainfall in the relation of cause and effect is in the last degree questionable. There is not the least reason to think that the regime of the winds and rain can be permanently affected so easily, or that any progressive change is going on so rapidly as to make itself felt in a decade of years.

GELATINOSINE.—This product is obtained by boiling pine wood under pressure in a solution containing sulphurous acid and magnesia, in proportions of about 1.4 per cent magnesia to 4.4 per cent acid. The solution is then diluted with four times its volume of water, and muriatic acid is then added to it in sufficient quantity to saturate one-half of the base present. A gelatine solution is mixed with the acidified decoction, the proportions being about 10 pounds dry gelatine to 12 gallons of the wood decoction. The precipitate which forms is the gelatinosine, which is separated from the liquid and washed. Alum may, in some cases, be employed instead of the muriatic acid, as above. When either of these ingredients is used it is not necessary to mix them first with the wood decoction, as they can be added simultaneously with the gelatine solution. Alumen can be substituted for the gelatine and the obtained product is then called Alhologinoine. The two products are said to be applicable as mordants for dyeing and also for sizing purposes. The discovery has been made the subject of an English patent.

A NEW ELECTRO-MAGNET.—M. A. Ricco, of Palermo, has invented a very original electro-magnet. He rolls a long strip of sheet iron around a nut of soft iron, placing oiled paper between the different layers of the strip to isolate them. A pole is connected with the nut to which the inner end of the iron strip is soldered, while the other is connected with the outer end. The current passing through the strip magnetizes not only the nut, but also each layer of the strip of iron, which plays the double role of conductor and magnetic substance, so that the lines of power produced by the conductor are condensed. It is stated that the power of such a magnet is considerably greater than that of an ordinary electro-magnet.

A NEW POISON.—From the decomposing masses of animal flesh Prof. Briggs, of Berlin, has isolated a very violent poison, which analysis proves to be a hydrochloric salt of a new base, and which did not resemble any other known combination.

PLANTS AND SUN HEAT.—HEIT J. Wortmann produced curvatures in growing plants by causing radiant heat to strike on one side only. Sometimes a plant bent itself toward, but in other instances the plant curved away from the source of the heat.

Passing Events.

News from the mining districts, aside from what we give in our summary, is not specially interesting. The situation at Tombstone is unpleasant. Many of the mines are remaining shut down and many of the miners leaving. Great crowds of men are still going to Idaho to the new camps there, and many, as ought to be expected, are returning disappointed. They give the region a "black eye," while others are as hopeful as ever. As yet no very startling discoveries have been made this spring. They seem to have been more lucky with lode than with placer mining discoveries.

The Secretary of State has received a dispatch from our Minister to Mexico, announcing that the President of that republic had, in accordance with a decree of the Chamber of Deputies, given effect to the appropriation of \$100,000 to defray the expenses of the Government of Mexico at the World's Industrial and Cotton Centennial Exposition at New Orleans.

The Cloverdale *Reville* says that the San Francisco and Clear Lake Railroad Company has just completed the purchase of upward of 5,000 tons of steel rails, sufficient for the entire road from Napa to Clear Lake.

The Union Pacific Company expect to haul 30,000 tons of Anaconda copper ore from Butte, Montana, this season. The company is sending that amount to Swansea, Wales, to be worked.

Mill Samples.

In order to determine the percentage to which silver ore is worked in a mill it is necessary to carefully assay the ore by sample. The mill sample is taken usually by allowing the crushed ore as it comes from the battery to run into a pail which is held at the end of the trough or apron leading from the batteries to the tanks. In a well regulated mill a sample is taken every hour or half-hour, depending on the richness of the ore, and the accumulated samples taken during a single day are dried and thoroughly mixed, and the sample taken in the usual manner for assay.

Car samples and mill samples always differ greatly in yield, and the former is invariably higher in value. It is reasonable to suppose that this finely crushed material, being intimately mixed by the process, should furnish a fairer average; nevertheless the value of the mill sample depends entirely on the manner in which it is taken. Not only may it chance that the sample is caught just after an unusually rich or poor shovelful of ore has been supplied to the battery, but accident or neglect of proper precaution may affect the value of the assay. The dish or vessel placed to catch the crushed ore should not be allowed to become more than half full, and no water should be permitted to run over, as concentration would ensue immediately. It may happen that the trough is placed unevenly, so that more water runs off at one side than the other, and unless the sample represents the whole stream its value is likely to be greater or less, according to the part where it is taken.

In some mills the samples are taken from the pans after the sand has deposited itself there, by means of a troyer. Mr. James D. Hague, in investigating the subject, concludes that not only may accident determine the value of such a sample, but in the sand of the tanks the value of the slimes that have passed on without depositing themselves, and which are often quite rich, is not represented.

In a well arranged mill the wet pulp is discharged from the batteries and conducted by means of a trough into settling tanks, where it collects, care being taken that the sand is deposited in those tanks immediately behind the pans. The rear tanks can be used to settle the slimes or lighter material carried in suspension. Before the pans are discharged, sand is shoveled out of the tanks in front of the pans ready to charge them. This is the last opportunity which is afforded to sample the pulp. Of course it must be borne in mind that should a large quantity of rich slimes be run into the pans simultaneously it is almost practically impossible to get accurate tests of the ore. Where the slimes alone are to be worked they can be tested by sampling after settling; or where the slimes have been allowed to settle in the tanks and that material is charged with the rest of the pulp simultaneously, there is no difficulty in ascertaining the value of the material charged. Assays should always be made in duplicate. Not more than a half ounce is ever requisite for ordinary ore. With rich ore, quarter ounces assays are sufficient.

In cupelling buttons in the muffle furnace there is more or less loss. Very careful assayers place a specified amount of silver of known quality with lead in another cupel with the hatch of cupels in the muffle, and determine its actual loss, which amount is added to the other buttons. It has long been understood that the silver bars brought here are usually "understamped"—that is, they are more valuable than appears by the stamp of the local assayers or mill assayers. A great many thousand dollars have been made and lost by the different parties in handling these bars. It paid Flood and O'Brien to establish their own refinery in this city to handle their own metal from the bonanza mines.

Taking samples from the pans when charged with ore before the quicksilver is added does not answer very well, though it is often done, because there may be quicksilver or amalgam in the pan from previous charges, and there is liability of error. The system of sampling from cars or wagons, so commonly done on this coast, will not give results which show a true average. Taking the samples with a "troyer" from the settling tanks, or from the thoroughly mixed ore before it goes to the pans, will probably give the best results, when the slimes are considered as well.

The Quartz Mines.

Some two or three months since one of the papers published in Stockton called attention to the deposit of quartz sands in Dry Creek, a tributary of the Mokelumne, and urged the farmers of the foot hill valleys to take measures to suppress the "nuisance." The quartz sands of Plymouth and Amador City do not, however, reach the San Joaquin, but the operations of the great quartz mines on the mother lode, who dump their tailings into the tributaries of the San Joaquin, in combination with the operations of a small hydraulic mine at Jenny Lind, Calaveras county, was magnified into a great grievance, threatening the navigation of the San Joaquin. There has been, however, no more complaints of the operations of the quartz mines referred to.

There are also in our central and northern counties great quartz mines whose sands must necessarily at some time reach the navigable rivers, and it becomes them to reflect upon possible consequences. Such mines as the Sierra Buttes and Plumas Eureka use, we are informed, more than 100 stamps in their own mills, besides employing part of the season all disengaged custom mills. The capacity of each stamp is about two tons per day, and as the crushed quartz passes through screens punched fine enough to equal 3,600 apertures per square inch, and it is estimated there are 2,000 stamps running constantly in the counties where hydraulic mining is prosecuted to a greater or less extent, and fine matter goes further than coarse, quartz miners cannot be disinterested.

Should the principles of the Sawyer decision be maintained by the U. S. Supreme Court, quartz mining will be vulnerable, for, says the Judge, in his opinion, "The United States have not attempted or intended to confer upon the defendants any right or privilege to foul or fill the waters in question," and in conformity to that opinion he in his decree enjoins defendants "from causing or suffering to flow into said rivers, creeks, or tributary streams aforesaid therefrom, any of the tailings, boulders, cobble stones, gravel, sand, clay, or refuse matter resulting or arising from mining thereon. And, also, from allowing others to use the water supply of said several mines or mining claims, or any part thereof, for the purpose of washing into said rivers and streams any earth, rock, boulders, clay, sand, or solid material contained in any placer or gravel ground or mine."

This opinion and decree would have closed every quartz mine on the line of the defendant's ditches, had any been using their water, and it is now a bar to their sale of water for such purposes. The quartz miners will scarcely wait until they are in immediate jeopardy, but will probably unite in aiding the appeal in the Woodruff case, so as to remove the possibility of future trouble.

Gold Washing.

Throughout Central Asia about the following system of gold washing is pursued: A framework of light willow poles, with a convexity of about 35 degrees to the horizontal plane, takes the place of the usual washing box. Upon this framework, firmly fixed in the ground, is stretched a blanket or carpet to catch the auriferous alluvium. In order to retain the gold, which has, of course, a greater specific weight, thick horse-hair ropes are sewn along the whole length of the blanket. The frame being now ready, a bag full of ore stuff is emptied into it; water is then poured on, and stirred with a small stick, whilst stones are thrown aside. When thus a few hundred pounds of alluvial soil have been treated in this way, the men proceed to collect the sediment adhering to the blanket. For this purpose the blanket is taken off the frame, folded in several thicknesses, and subjected to another washing in the following way:

A wooden bowl or trough, large enough to contain the folded blanket, is placed in a small bay of the river where the current is slack. The workman removes the blanket, fold by fold, and washes it, allowing the sediment to collect at the bottom of the trough. Having accomplished this, he takes the bowl in his hands and moves it rapidly, with sudden jerks, to right and left, splashing the water and the lighter soil over the sides. From time to time more water is added, and the work is continued for several hours without intermission. As the gold in the bowl gradually detaches itself from the particles of sand mixed with it, the movements of the workman become more and more artistic and careful, his whole object being to leave nothing but the pure gold, however small the quantity, in his bowl. When this has been obtained, he dips a finger into the water and flicks a drop or two into his bowl, pouring them out, together with the gold, into a separate porcelain cup. This finishes his day's work.

The Fish Interests of California.

At the last meeting of the California Academy of Sciences, Mr. Joseph D. Redding, State Fish Commissioner, read a paper on the above subject, treating it from an economic standpoint, and not attempting to go into the mysteries of fish-culture. He referred to the geographical position and physical peculiarities of California, which gave it unrivalled advantages, not only for commercial and agricultural purposes, but for pisciculture. Within the past quarter of a century, fishing as a means of a livelihood, wherein each successful haul exhausted so much of the capital has developed and elevated itself into an industry ranking all others in the prolificness of its returns and the greatness of its possibilities.

The Commission of fisheries of California was appointed under an act of the Legislature, entitled, "An act to provide for the restoration and preservation of fish in the waters of the State," approved April 2, 1872. The gentlemen who first composed it devoted several years of arduous and enthusiastic labor, without compensation, to the subject, and to these gentlemen we are indebted for the progress our State has made in fish culture. Many choice varieties of fish have been introduced successfully, especially the shad, which is already beginning to fill our markets, and in one or two years will be as abundant and as cheap as the salmon. It has been proven that most any variety of fish can find a congenial home in our waters. The commission, with the assistance of the United States Fish Commission, has had hatched and deposited in the headwaters of the Sacramento and tributaries, within the last ten years, over 15,000,000 of young salmon. The result is that the Salmon catch in the Sacramento river has been marked and regular. This catch for 1875, was 5,098,000 pounds, in round numbers; for 1876, 5,311,000 pounds; for 1877, 6,490,000 pounds; for 1878, 6,520,000 pounds; for 1879, 4,432,000 pounds; for 1880, 10,837,000 pounds; for 1881, 9,600,000 pounds; for 1882, 9,605,000 pounds. This shows a general and continuous increase, with certain fluctuations incident to extreme droughts, or other natural disturbances.

Many streams have been replenished with our native and imported trout, by the efforts of the commissioners, and they have succeeded in passing important laws for the protection of the fish, during the spawning season; but the whole work up to the death of Mr. Redding, had been experimental. As he often remarked: "We are but on the threshold of this work. We are just beginning to find out what California can do in fish-culture." We fully appreciated that the object of the commission was not merely to stock our mountain streams and rivers with choice varieties for the sportsman and for the table, but to show to the people that it lies within their power to take a leading place in the commercial department of fish industry. Four things, at present, militate against the development of the salmon-canning industry, as well as the general progress of our fish interests: I.—The presence, in vast swarms of seals and sea lions at the Golden Gate. II.—The debris in the Sacramento river. III.—The universal disregard of the fish laws on the part of the fishermen themselves. IV.—Dams across streams.

The fishermen, especially the Chinese, wantonly destroy myriads of young fish, and the laws, as they now stand, are unavailing to reach them. The violation of the fish laws should constitute a felony, instead of a misdemeanor, and they should be enforced. We have all the experience and discoveries of older countries to aid us, and were we to seek the world over, there is no place that can compare with the Bay of San Francisco and the surrounding coast for natural advantages, with which to develop this new industry. The original members of the California Commission have accomplished a great work, and their reports are quoted as a standard authority. It now remains for the people of the State to take advantage of what has been shown to lie within their power. We have been first in the production of the precious metals. We are outstripping all other countries in the productions of the soil. We can easily take the lead in the products of our waters.

Fishermen will not obey the laws, and the laws themselves are inadequate. The \$5,000 appropriated by the Legislature could be easily spent for the single purpose of prosecuting violators of the fish laws on the Sacramento river. With so small an appropriation, what investigations and experiments can we make, in regard to our marine fishes and their culture, a branch of the industry hitherto untried? An appropriation of \$15,000 a year, at least, is needed, and it is very small indeed when we consider to what advantage it could be spent. With it we could establish our own salmon-hatching station on the McCloud and turn into the streams 10,000,000 of young salmon yearly. We could employ experienced deputies, clothed with the powers of sheriffs, to patrol our rivers. We could build ponds for black bass and white fish, and have three or four hatcheries for trout throughout the State.

Utilization of the Exhaust Steam in a Stamp Mill.

[Written for MINING AND SCIENTIFIC PRESS BY E. GUTZKOW.]

I wonder sometimes how many of the millions who travel in steam cars, proud of the aerit of being born in this fast century, and feeling a kind of proprietary interest in the invention of steam power, think of the opinion which future generations will hold this invention in. If one of us could return to this world in, say, 300 or 400 years, he would probably hear the historian of that period explain how the nineteenth century was distinguished by a certain cumbersome contrivance, still occasionally met with in some museum, called the steam engine, by which the people of those times managed to get a few per cent from the force of burning coal, and for that purpose depleted the earth above and below the surface of its never-returning fuel treasures.

The greatest portion of that waste of heat passes off, as everybody knows, in the exhaust steam. As long as no great inventor appears and teaches us how to convert that lost heat into force, propositions by which we can at least save it for other purposes ought to be always in order. This encourages me to give in the following some suggestions how, in a special case, in a stamp mill for roasting ores, the exhaust steam could be utilized. In stamp mills of that kind the ore is crushed dry, because it has to undergo roasting before further treatment. That this dry crushing is, on this coast, done by stamps, and not by rollers, as elsewhere, is due to our fondness for our California stamp mill and for mechanical roasters which require great fineness of the ore. There are, however, many drawbacks in dry-crushing as compared with wet-crushing. I will not dwell on minor matters, for instance the heating of the stamps, the dust, the short life of the sieves, but the necessity of drying the wet ore as it comes from the mine is a source of much annoyance and expense, and the greatest objection is that the output is very much smaller, often only one-half of that from wet crushing; that is, a mill of 40 stamps may crush 100 tons of ore wet, and only 50 tons dry. It is apparent that, if we crush our ore wet and could dry it in a cheap and practical way by our exhaust-steam otherwise wasted, we would save half of our plant in stamps, and also much in the size of our engine, the number of our boilers and in the fuel to run the latter. In order to prove that this proposition is quite feasible it will be necessary: 1. To calculate the moisture in the wet pulp. 2. The heat at disposal in the exhaust-steam. 3. To explain the apparatus required and to give some figures from actual experiments.

Ad 1. The water retained in the wet pulp when taken from the settling tanks is much less than a casual observer will think. Rittinger, an excellent authority, states it to be 20 per cent for coarse ore and 25 per cent for slimes. I find that an addition of 30 per cent of water will convert any ordinary quartzose ore that has gone through a No. 40 sieve into a thin pulp. This will correspond to the evaporation of 3 tons of water for 10 tons of dry ore.

Ad 2. In an average steam-engine between 20 and 30 pounds of steam are consumed hourly per net horse-power. In a 50 horse-power engine between 24,000 and 30,000 pounds of steam escape daily with the exhaust. As one pound of steam may, theoretically, evaporate one pound of water the above quantity of steam could deprive 40 or 50 tons of wet ore of its moisture. In practice, of course, it will be less; the amount required to heat the boiler-feed-water has also to be deducted. Still, in an apparatus like the one to be described, where the steam acts on an enormous surface and the wet pulp spread in a thin layer presents to the atmosphere a correspondingly large area, the effects of steam as fuel is remarkably high.

Ad 3. I had yet no opportunity to experiment with ore on a large scale, but happened to gain considerable experience with the drying of another substance under very similar circumstances. Some years ago I introduced the utilization of "bittern," the mother liquor from the making of sea-salt at some works in the vicinity of this city, and had to manufacture from it daily about 400 pounds of carbonate of magnesia. This substance is distinguished by large absorbing power for liquids, and is consequently used in making certain nitro-glycerine compounds. The pulp which I retained on a filter held not less than 15 pounds water for one pound of dry substance. As it was not advisable to remove part of this water by mechanical means, I had to evaporate every 24 hours fully 6,000 pounds of water contained in about 100 cubic feet of pulp. This was done by the exhaust from an eight horse-power engine, or, rather, as the engine happened to be a strong steam-eater, by an engine consuming 60 pounds of coal per hour.

The steam dryer is made entirely of wood and galvanized iron. I do not claim for it any novelty. Similar ones have been in use for drying salt for a long time. Still, it is so cheap and effectual, that it will well bear a closer description. The galvanized iron coming in sheets seven feet long, a table is formed about one foot over the intended floor level of joists and

tongued and grooved redwood boards, one hundred feet long, and seven feet wide. All around a rim is laid of four by six redwood beams, halved together six inches high. A long scantling is nailed lengthwise in the centre, as auxiliary support for the iron sheet. This is prepared on the place in one piece for the full 100 feet of galvanized iron, No. 20, riveted together, the holes one inch apart, turned to bring the flat side of the rivets uppermost, spiked down into the four by six redwood beams, with galvanized 20-penny nails, soldered where necessary. Now, only a two by four scantling has to be laid, covering the nail heads, and forming a rim all around, and every three feet a three-fourth-inch bolt driven through rim, sheet and table, and the whole is finished. This dryer, which required no repairs thus far, cost \$150 for sheets and plumbing, and as much for lumber and other labor, or \$3.00 per running foot.

require a more solid construction of the drying table and more labor. If the apparatus is expected to do as much work for ore as for magnesia, it would answer for drying ten tons ore daily, and the ore pulp would stand two and a half inches high. Perhaps it would be necessary to run the dry ore through some light Corrish rollers to break up any lumps formed, when the salt, if required, may be mixed in. Of course salt ought not to be mixed to the wet ore.

I need not go into further details. Every millman will see that the plant could be placed about side the settling tanks, and that the spreading and discharging of the ore can be facilitated by mechanical contrivances. Of course I do not expect that foundrymen will take kindly to an innovation which tends to reduce the plant of an ore mill. There is no fighting against human nature. Neither will the

UPPER WOOD RIVER MINING REGION, IDAHO.

There were two of these drying tables, making, with \$400 for the commodious shed, \$1,000 the total cost of the whole concern.

I would not have succeeded in making the little steam at disposal, do all what was required without a contrivance which is possibly new, although plain enough. The two drying tables were placed side by side, four feet apart. The exhaust could pass under either. The outlet was close to the inlet, the drying chambers under both tables at the further end in connection by four-inch pipe. Thus, by opening or closing suitable stopcocks, the steam passed under the 200 feet of drying table, and could be reversed. By methodically charging with wet pulp and regularly changing the steam current once every twelve hours, the steam would always meet the most dry pulp first and the least dry last. The pulp is spread about one inch thick. One man who has other work for the rest of the day attends to it the first thing in the morning and the last in the evening. Each charging and discharging takes one hour, or two hours for both pans every twenty-four hours.

In applying these facts to the drying of ore pulp it must be borne in mind that magnesia, which retains after drying almost the full bulk of the wet pulp, and is consequently a very light and porous substance and an extremely bad conductor of heat, presents one of the most unfavorable conditions. On the other hand, the rougher handling at an ore mill would

circumstance that no patent is attached to my proposition serve as a recommendation, because no capitalist thinks much of an idea he need not pay for. Still I hope that some time somebody somewhere will give it further attention.

The Wood River Country.

That portion of Alturas county, Idaho, known collectively as the Wood River Country, is still in its infancy as a mining section, but the number, size and richness of its lodes, the facility with which they can be opened and worked, and the natural advantage of the region in respect to wood and water, have brought it rapidly to the front. Wood River takes its source in the same range of mountains as the Salmon river, the latter flowing to the north, and Wood River in a southerly direction, to its confluence with the Snake river. The mining camps are scattered along the river.

Galena district comprises the mining section at the head of Wood River, with the town of Galena as its supply depot. The accompanying map, together with a few notes, we take from the last report of the Director of the U. S. Mint.

The chief group of mines is the Senate group, owned by the Senate Mining and Smelting Co. The Senate, Red Cloud, Chief, None Such and Kid mines, constitute this group, and are all

rich and permanent looking prospects. The property of the company is in good shape for successful and prosperous operations. They have a smelter. They have also the Scorpion claim, a valuable lime quarry, which provides flux for the smelter.

The Conway Castle, President, and Delta, adjoin the Senate and Red Cloud, and are the property of the Conway Castle Mining Co., a New York organization. A tunnel has been run on the vein of the Conway Castle. A continuous vein has been found in the President. The company have constructed good roads, blacksmith shop, boarding house, etc.

Important discovery is the Dresden. The ledge has a prominent cropping of white lime, which is traceable for 2,000 feet, and so far wherever this cap is removed the galena appears.

Death of Colonel Williams.

Colonel A. F. Williams who has since early times been connected with the mining interests of this coast—and particularly those of California—died at his residence in Oakland on Wednesday. Colonel Williams came to California in 1850. As he was a professional civil engineer he pushed into Nevada county, where he engaged in surveying and constructing mining ditches, a business he has followed ever since. He brought the first water into Oroville and also constructed the laying ditches in Nevada county. From Nevada county Colonel Williams went to Sierra county in 1852, where he engaged in constructing mining ditches in the vicinities of Pine Grove, Howland Flat and La Porte. He was one of the original owners of the Blue Gravel Mining Company of Smartsville.

About four years ago, in company with a number of capitalists of Alameda county, the Colonel sent out an expedition to Alaska for mining purposes, an enterprise in which he took an active part. A schooner was purchased and the expedition started off under command of Col. Williams. Ledges of galena were found, and arrangements made to work them. Some ore was taken out for shipment to this city. The vessel belonging to the expedition was wrecked on Golovin bay. In open boats the prospectors and crew proceeded to the islands of St. Michael, a distance of several hundred miles. The shipwrecked party were taken from the islands by the United States revenue cutter Corwin, and were brought back here. Last spring the Colonel fitted out another expedition to Alaska, but his health prevented him from making another sea voyage, and Mr. John Lawry, of Centerville, was placed in command. Nothing has been heard of the result of the last expedition, but news will probably reach here this fall. Colonel Williams was a man of energy and good practical sense. He was well liked by all his associates, and upright and honorable in all his dealings. He was 72 years of age.

Tests for Ores.

From a chapter on "Tests for Ores" in a little work on "Assaying Gold and Silver Ores," by C. H. Aaron, (published by Dewey & Co.) we take a few paragraphs, as follows:

Silver.—Powder, mix about a grain with twice as much fine lead (free from silver), soda, and borax. Moisture with water, place in cavity scooped in pieces of charcoal, smelt by blow-pipe flame, cupel the bead, examine bead with lens, if large enough to handle, part for gold. Or, powder, roast, boil in glass or earthen vessel with a clean strip of copper, bluestone, salt and water, gives a white coat on the copper. (Nearly all silver ores will do so if boiled with bluestone and salt, without roasting.)

Gold.—Powder, roast if sulphurets are present, grind very fine and wash in pan or horn, examine with lens; yellow flattened particles not dissolved by nitric acid.

Copper.—Powder, moisten with salt brine and throw into fire; an intensely blue flame. Or, moisten with muriatic acid, and direct blow-pipe flame on it; the same. Or, roast, steep in ammonia; a blue solution. Or, boil in acid and add ammonia; the same.

Lead.—Powder, mix about one grain with four grains of soda, a little borax, and water to moisten, place on charcoal and melt under blow-pipe flame; gives a malleable, metallic globule, which when melted on a cupel gradually disappears, leaving a yellow stain and perhaps a bead of silver; or a coat on the charcoal which is dark lemon-yellow hot, sulphur-yellow cold; disappears on being heated but not touched by the blow-pipe flame.

A BIG MINING SUIT.—A big suit between the Albion Con. Mining Company and the Richmond Mining Company, of Nevada, has been set for trial in the District Court at Eureka, on June 9th. The suit was commenced in May, 1882, and is for the recovery of 5,000 tons of ore or its value at \$100 per ton, aggregating \$500,000; and also for \$50,000 damages alleged to have been done to the Albion mine, making in all \$550,000, for which the Albion Company asks judgment against the Richmond Company.

In April the Denver & Rio Grande took east to the Missouri river 3,828,000 pounds of Utah bullion. The road carries one-third of all the bullion product of Utah which is sent East.

Nevada a Good Country Yet.

There are some people living in this State who have much confidence in it, and the editor of the *Reno Gazette* is one of them. He says: "The State of Nevada is under a temporary cloud, but there are some things about it which must not be forgotten—some things which sharp business men should always keep in sight. It has not yet been a State twenty years. It has never contained more than 65,000 people, yet it has yielded more gold and silver, and paid more dividends from its mines than any other three or four States or Territories combined, except California. Its people have purchased from other States and Territories more material than the same number of men ever purchased in the same length of time; and it has paid in gold and silver for all it has bought. The bullion of Nevada between 1860 and 1864, acting as a lever in the national finances, did more to uphold the credit of the country than did the product of the most powerful Eastern States; and because of that product and the product of California and the interior Territories those in power had the material with which to meet the country's interest obligations—the courage to commence to pay the mighty debt, and finally to bring around resumption and a reduction of fifty per cent in the rate of interest. A State which has been so important, which still remains with but two or three exhausted mines, and with plenty of others which have never yet been more than surface-scratched, should not be dismissed with a sneer. It must be borne in mind, too, that a great many of the camps of Nevada have been worked from 100 to 250 miles from the railroad, and all kinds of mining supplies are 100 per cent higher than they would be if proper railroad facilities extended throughout the State. If under such circumstances Nevada has been made to pay, there must be some unusual merit in its mines, and the time will soon come when Nevada will again take her place at the head of bullion producing States. Its gold and silver are not its only minerals. There are besides, vast beds of iron, horax, gypsum, sulphur, copper, antimony, lead and many other valuable minerals, which are more used than either silver or gold. It is only a question of time when all these resources will be looked after by the shrewd men of capital who will build railroads, erect reduction works and open up to the people a new era of prosperity, increase the population, enhance the value of property and make us feel that Nevada is one of the great States.

THE POLARIS STRIKE.—It is quite certain that the recent developments in the Polaris mine at Columbia will give an impetus to mining operations never heretofore experienced in that section. There are scores of other ledges in the immediate vicinity which prospect as favorably on the surface, and which are likely to prove as valuable when developed to the same extent. If the reports of the Polaris strike are correct, it is the most extensive and important one ever made in Eastern Nevada, and making allowance for the enthusiasm of those who have examined it, it is perfectly evident that it is of sufficient importance to justify the prosecution of more active and extensive operations than were ever before projected in the district. The following is the result of seven assays made here yesterday from ore from different portions of the ledge. They were taken from various points in the workings and from different classes of ore, with a view of obtaining reliable information in regard to the respective values. The following is the result: No. 1, \$249.93; No. 2, \$1,509.20; No. 3, \$181.35; No. 5, \$645.88; No. 5, \$62.33; No. 6, \$63.26; No. 7, \$590.20; average, \$471.16.—*Tuscarora Times-Review*.

MINERAL STATISTICS.—A Blue-book on the mineral statistics of the United Kingdom for 1882, prepared by her Majesty's Inspectors of Mines, has just been issued. The general summary given of the mineral produce in Great Britain and Ireland in 1882 shows that during that year were raised 156,499,977 tons of coal, of the value (at the mine) of £44,118,400; 226 oz. of gold, realizing £863 at the average market price, and 372,544 oz. of silver, of the value of £80,426. The quantity of iron ore raised was 18,031,957 tons, representing a value of £5,779,285 at the mine, and of metal contained in this ore 6,513,281 tons, of the value of £18,237,186. The total value of the minerals raised in 1882 was £54,879,507, and of the metal contained in the ores £20,558,050.

A GOLD-SAVING MACHINE.—The *Tuscarora Times-Review* says: Sam. Mazingo and Mr. Kenney, of Battle Mountain, have a gold-saving machine, the latter's invention, which they intend in a short time to take over to Snake river for the purpose of experimenting with the fine gold in those placers. It is to be placed at the end of sluices, and is something on the principle of a rocker, which can be worked either by water, steam, horse or even man power. From the results of experiments already made, the owners are confident that there is no gold so fine that their machine will not save it. An application for a patent is on file.

NITER.—There is quite an excitement down at Big Meadows about the Hunnhold niter beds, eight or ten miles south of Lovelock on the Central Pacific. The deposits have been located for a distance of four or five miles, and notices of a great many claims have been filed for record in the County Recorder's office.

The Sierras and the Himalayas.

[A Comparison Between the Forests of the Sierra Nevada Mountains and Those of the Himalaya. Translated from the German of R. Von Schlagintweit by Professor Granville F. Foster, for the *Reno Gazette*.]

Among the many beauties of California, the forests, that magnificent ornament of the far-stretching and mighty Sierra Nevada, occupies one of the most prominent positions. Although the transient view of the same charms the tourist as he is whirled in rapid flight over the Pacific railroad, yet it is well nigh impossible for him to have even a suspicion much less any correct idea of the sublime and charming wonders of nature which would unfold themselves at every step before his astonished and delighted gaze in inexhaustible profusion, should he happen to leave the train sometime during the summer months at any one of the stations which lie high up in the mountains, and thus to seize upon one of the many opportunities which here so often present themselves to learn by closer view the interior of the country.

More than once in such excursions would the forests of California forcibly recall to mind those in that loftiest range of mountains, the Himalayas (which I have also visited) and at such times would I be led to make the comparison between them which I here append for the benefit of the reader.

We find in the Sierra Nevada that the natural

which surround it jealously, which rob it of its choicest juices, which deprive it of the space necessary to its complete development. In this

Complete Development in the Forests of California

Can the trees be seen, the eyes resting, well pleased and delighted, on the dark green of the leaves and indeed upon the harmonious blending of colors in all parts of the trees themselves, while the glory and beauty of these become enhanced by a carpet beneath, most gorgeously woven out of numberless rich-blooming flowers, magnificent both as to form and color, and out of a large variety of grasses, most delicate and beautiful both as to shape and hue—a carpet with which the forest floor in this region is almost always adorned. But in a tropical forest each plant-form continually strives to supplant and to kill out every other form. No tree there can attain to its greatest size or reach its complete development, since between the numberless twigs and branches of the tree itself, there twist and wind in manifold forms, in thousands of varieties, twining plants, ferns as tall as a man, besides which there is a prodigious growth of parasitic plants. The tropical forest is overpowered, hardened by the very superabundance and luxuriance of its own plant-forms. Fruitless indeed will be any endeavor on our part to discover in tropical forests the least trace of regularity. There rules there, on the contrary, a chaos, an irregular mass, a perfect confusion of trees, shrubs, grasses, climbing, and parasitic plants of every kind and variety. There, too, will the eye soon tire, not the less because of the glaring, obtrusive colors which

that which collects in the lower or deeper-lying places, in ponds, or more truthfully in sloughs or puddles, does not refresh when ingested. It is warm, instead of allaying, it increases thirst and when used in large quantities, excites a general malaise, which often instead of soon passing away, leads to high and violent fevers, or to some other of the dangerous diseases. It can only be used without detriment to health when hoiled, or after it has undergone the tedious process of filtration. As we wander through the pathless jungles, a gloomy sadness seizes us when we reflect what sovereignty man possesses, even when his knowledge and capacity for labor have been tested to the utmost over this particular world, so at enmity with him.

But from every point of view, what a different picture do the forests of the Sierra Nevada present! What a striking but charming contrast. Here blows a clear, pure, refreshing, animating and strengthening wind; now here, now there, bubbles up from the earth beneath, springs of the most precious waters—clear and pure as crystal; now here, now there, pours over the rocks a roaring torrent. In the Sierra Nevada and still more in the Himalaya (which, from their great height, we do not reckon as tropical in their flora) it frequently happens that different circumstances combine to lighten into still greater degree the natural beauty of the forest. The climate, as in the Sierra Nevada, is simply glorious; no cloud in summer ever obscures the deep blue vault of heaven, and the temperature of the air is neither too hot nor too cold. Now, between trees, flowers and the most luxuriant green, we enter some narrow valley. Traveling along this valley, we

SCENE IN THE HIGH SIERRAS OF CALIFORNIA.

glory of the forest is greatly heightened in the summer season by an over-arching sky never for once obscured by clouds—a sky which in purity, brilliancy and splendor, equals that of tropical regions, without ever consuming us in its glowing fervor, as does the latter. In the Himalayas, and in the Sierras, are trees which seem to possess a correct presentiment and thus fearful lest otherwise they might have been seized by the powerful and equally destroying as well as creating hand of man, and thus made to breathe out their tender lives beneath the strokes of the woodman's axe, are found growing on precipices so steep and so inaccessible, that possibly the feet of man may never be able to tread thereon. In both regions,

A Fragrant, Balsamic Air,

which we breathe with indescribable delight, whistles gently at all hours during the daytime in these magnificent forests, through which there constantly passes a mysterious whispering and rustling. Especially in summer, when in California the days are almost continually cloudless, are the evenings even in those forests, which reach an altitude of 6,000 feet, incomparably beautiful, since, at that time of the year, there is a rich and varied vegetation, and in the evenings rather than during the daytime, the very air seems loaded with the perfume of myriads of odoriferous shrubs and flowers.

The various kinds of coniferous trees, which, spreading over vast areas in magnificent forests, adorn the crests and declivities of the Sierra Nevada, form equally well a "primeval forest" as do the thickest jungles and far-stretching forests of India at the base of the Himalayas, or those of Southern and tropical America. But how vastly different is such a forest in California or in the higher Himalayas, from a tropical one! In the forest region of California each tree grows to its full perfection, since there is no profuse growth of climbing plants, no powerful ferns, no troublesome parasite plants

the leaves present on all sides than in consequence of their myriad forms and their total lack of regularity. It is impossible to avoid the sad conviction which obtrudes itself forcibly on the mind that here the vegetable kingdom develops its plant-forms in such a manner that the noble and perfect ones are oppressed and stifled, while on the contrary, in opposition to all the laws of harmony and beauty, the common and lower forms are favored and assisted. It is not there the survival of the fittest, but of the hardest and strongest which obtains there.

Just in the same ratio as we in California search with the most pleasant of anticipations for every place in which the giant trees lift up to heaven with joy their lofty forms, so do we avoid on the contrary just as much as possible any lengthened delay in tropical forests, not because of any apprehension of any unpleasant meeting with the fierce and ravenous beasts that make their habitat therein, but simply from the natural disinclination to expose ourselves to influences highly pernicious—in the prejudicial to health—influences which here bear full and complete sway over us, against which we cannot oppose anything with any hope of success, our knowledge here completely failing, leaving us well-nigh powerless and defenseless.

Beauties of the Sierra.

The atmosphere of tropical forests is of itself full of vapors, is humid, oppressive, sultry and is further rendered pestilential by miasmatic vapors, exhaled from enormous masses of decaying vegetation. The ground is constantly moist, oftentimes covered inches thick with plants, leaves, broken branches, all lying prostrate in the mass and seething with corruption. Beneath these fallen materials, sometimes quite covered with them, and often thus hidden from the eye, frequently steal along muddy and slimy streams, or occasionally water in the form of isolated brooks. The water of these streams, as well as

come at length, suddenly and unexpectedly, to a head in the same, passing which, and behold! before us stands one of those most sublime of mountain peaks (of which there are so many both in the Sierra Nevada and Himalaya) rising thousands of feet, and clothed with the most dazzling, blinding white snow, creating one of the most brilliant and beautiful contrasts, between the pure, dazzling white, on one hand, and the delicate tints of green which surround us on all sides in the valley. Our guides, the Hindoos, prostrate themselves to the earth, and we hear them devoutly murmur their low-spoken prayers to the supposed Deity that resides on the mountain summit. Even we are greatly affected, and stand captivated and charmed in speechless admiration. The appearance is so sudden, so unexpected, and at the same time so imposing, that it produces in us a deep, overpowering effect, making an impression on our minds which nothing is able to efface. I can to-day vividly recall many such grandly beautiful scenes in nature, many of which I saw years since in the wide extended plain of the Ganges, as I turned my eyes in the direction of the mountains. It is just such scenes as these, which, making the Himalayas so beautiful, lend a peculiar, and to a stranger, a never-to-be looked-for charm to the landscape, which, in itself alone, is ever a sufficient compensation for all the trouble and fatigue which we are obliged to undergo ere it is possible for us to procure for our enjoyment so rich a pleasure; but as prodigally as the Himalayas have been endowed by nature with beauties, inexhaustible in quantity and kind, yet there is wanting there one of the grandest ornaments of the California forests, namely, those giant trees which appear here and there in a few places in the not so lofty, but not less beautiful, Sierra Nevada, known in California as the "big trees"—the old, venerable sequoias, at one time known in England as the *Wellingtonia gigantea*, and in America as the *Washingtonia gigantea*.

Gold-Saving Machines.

The Snake river placer mines have adopted what is known as the Edwards Gold-Saving Machine. It is described by the Idaho Register. In the Edwards machine, now in use here, the grizzly is laid about twenty feet in length in the sluice box, but what passes through falls into an under division or lower story of the same box, and this lower compartment has a solid bottom, except where one large hole or slot is left to let the water drop out. Now, instead of dropping to the ground, this water, containing, as it does, all of the gold and black sand, drops into a wide, flat and singularly constructed sluice box, which rests nearly flat on the ground. The water has to fall, say about two feet, into this last box, the main stem of which is at right angles with the upper box, about ten feet on each side, or like a cross. Imagine a box, or boxes, in the shape of a comb; this comb (box) has eight teeth, each tooth ten feet long and three feet wide, and pointing toward the river.

Now go back. The water from the grizzly drops into the flat sluice box; is spread out to each end of the (comb back) box, and through little gates is let into the (teeth) boxes. All of the last are carpeted with burlap cloth, and as the water runs shallow over the burlap, the gold and sand are caught in the nap or precipitated; the water passes out into the river. After about a day's run the burlap is taken up and washed out, like a dirty sheet into a tub. Still to the naked eye very little gold is visible. Quicksilver and acid are put into the tub and the gold is amalgamated. Some of the more advanced have a small arastra, built inside of a large tub made for the purpose. By this process amalgamation is more complete. It is claimed that ninety-five per cent of gold in the ground is saved. The cost of one machine, or system of boxes, is probably about \$100.

Ore in Small Lots.

The article in the MINING & SCIENTIFIC PRESS, entitled "Ore in Small Lots," seems to have been generally favored by our Idaho exchanges, and it is evident that all unite in upholding the practicability of the market therein proposed for ore in small lots coming from our smaller mines and prospects, viz: That market afforded by the business merchant, who, seeing a good profit in the accumulation of such lots, is willing to advance money on small samples that cannot be handled with profit by the larger dealers and reduction works. The merchant thus interesting himself in behalf of the prospector does an inestimable good to the community at large, and indirectly nourishes his own interests by effecting a more prosperous condition among the prospecting class, and encouraging the development of treasures that without this trifling aid would doubtless often lie hidden by the hand of poverty. There are many enterprising heads and able hands in nearly every mining community that are compelled to forsake the brightest prospects and often near fortunes in the want of a few dollars worth of provisions and tools necessary to carry on the work of development. Such men are usually enthusiastic and need only the stimulus of the most trifling, but most essential encouragement to continue in the earnest work that is sure to bring them a just reward. They are often found in the possession of a few hundred pounds or a few tons of rich ore, the sale of which would bring them sufficient returns to carry on the work of turning their prospects into mines, and the assistance afforded them by the community at large is just so much toward the public wealth.—*Ketchum Kystowne.*

THE FASCINATION OF THE GOLD MINES.—An old forty niner says of gold hunting: "It's the fascination of it. Lor' man, when you've struck it pretty rich and can see yer gold right in front of you; when you're piling it up every half hour o' day, with a nugget now and again as big as a bullet to cheer you, and when the evenin' comes and count it up and find a hundred odd dollars just picked out o' the earth that day—well, there ain't nothin' like it. Then when you don't strike it rich you always think you're goin' to next day, an' it's just as exciting hearin' other men tell in the evenin' what they pulled out as it is countin' over your own. Why, I've been three and four months at a time without makin' a dollar and without a cent in my pocket; but gee-whittaker! the excitement of it don't give a man time to think how hard up he is."

THE HOTELING IRON MINE repairs on the furnace of the mine are now nearly completed, and in a few weeks more at the furthest, it will be in full blast. During the winter the company have been manufacturing charcoal which they ran do much more rapidly than formerly for they have altogether something like sixty patent kilns and coal pits. During the late storms the roads were so bad that it was impossible to do any hauling but that difficulty has been removed. The output of metal, it is confidently believed, will be greater this season than in any previous year.—*Argus.*

THE NEW TAILINGS CONCENTRATOR.—It appears that the new concentrating apparatus to be used in working the big reservoir of tailings down on Six-mile Canyon, is the invention of Mr. Dillon, a Comstock mechanic, with improvements by Mr. O'Neale. The machine will separate the metallic constituents from the worthless sand very rapidly and cheaply.—*Virginia Enterprise.*

USEFUL INFORMATION.

How to Overcome the Destructive Moths.

This is one of the greatest vexations which careful housekeepers have to contend with, and their depredations are not to be remedied after they have once made inroads. Houses heated by furnaces are especially predisposed to have moths, but every housekeeper must be on the watch for them, for, from the time that the windows begin to be left open, the trouble begins. Heavy carpets sometimes do not require taking up every year, unless in constant use. Take out the tacks from these, fold the carpets back, wash the floor in strong suds with a tablespoonful of borax dissolved in them. Dash with insect powder or lay with tobacco leaves along the edge and re-tack. All moths can be kept away and eggs destroyed by this means. Ingrain, or other carpets, after shaking, are brightened by sprinkling a pound of salt over the surface and sweeping carefully and thoroughly. It is also an excellent plan to wipe off the carpet with borax water, using a thick flannel cloth wrung tightly, taking care not to wet it, but only to dampen. Open the windows and dry the carpet before replacing the furniture. Other woollens including blankets and wearing apparel, must be beaten and brushed and folded smoothly. Be careful to clean every grease spot with ammonia and water, not too strong, and a dark woolen cloth. Tie pieces of camphor into little bundles and put one in each article. Wrap the article in newspaper, as printer's ink is a great preventive of moths, and sew them up in strong sheeting bags, labelled, so that it will not be necessary to open them during the summer except for use. This is a good way for those who do not possess cedar boxes, and the articles need have no other care if every spot is treated as directed and the garments are not left hanging in the closet too long before putting away for the season.—*Providence Star.*

MULTIPLYING USES FOR WIRE.—Future analysts may well describe this period of American history as the wire age, says the Boston Advertiser. In no part of the economy of our daily life are we divorced from wire. It is our slave, and yet an ever present master. Sleeping, we repose on wire mattresses. Eating we see foods that have passed through sieves and which are sheltered from insect appetite by wire covers. Calling we pull wires to ring curled wire gongs. Traveling we are conveyed by cable or electric railways, hoisted by elevators hung on wires, and hurried over wire bridges. We announce our coming by telegraph or telephone wires, and we thread our way by night through streets lighted by means of electric cables. Across our fields are strung many thousands of miles of barbed wire fences, against which dumb brutes protest. Texas rangers draw the knife, and lawyers, judges and reporters whet their intellectual blades. Our clocks are set by wires, our watches run by wires, our books are stitched with wire, our pictures are hung by wires, and our politics managed by wires, and we add by wire-pullers.

WOOD PULP.—In the first stages of the manufacture of wood pulp for paper, poplar was regarded as pre-eminently adapted for the purpose, and for a considerable time it was thought that only that wood, basswood, and a few other kinds could be ground into a suitable pulp. Now, however, machines are made which turn out pulp with equal facility from all kinds of wood. The longest fiber is made from willow; basswood and poplar ranking next respectively. Cedar, fir and hemlock are said to work alike; maple has a fiber shorter than either spruce or pine, and is quite hard to grind; birch is very hard and grinds quite short. Poplar and buckeye pulps remain white for a considerable time, other woods changing color; birch becomes pink, maple turns purple, and basswood takes on a reddish hue.

COATING FOR STONE.—The application of alkaline silicates to the exterior of buildings to prevent the deterioration of stone has not been attended with satisfactory results. H. L. Kessler proposes to use a solution of fluo-silicates of bases whose oxides and carbonates are insoluble in a free state. When soft limestone is saturated with a concentrated solution of a fluo-silicate of magnesium, zinc or lead, a very considerable degree of induration is soon reached, and the resulting products, except the liberated carbonic anhydride, are less soluble than the stone itself. No varnish is formed, and therefore no danger arises from the expansion of frost beneath it. The process has resisted the severe tests of winter. Colors may be introduced satisfactorily.

A USEFUL PLANT.—In the French journal, *Larancie*, M. Paillex calls attention to a Japanese plant named *Kusu* (*Pueraria Thunbergiana*), the roots of which contain starch, while the leaves and shoots are used as food. Its fibrous portions are adapted for use in the manufacture of cordage. It is a lofty and hardy plant, attaining within a year to the height of between twelve and twenty-five feet. It yields fruit, and grows upon the most unfruitful dry ground, where nothing else would thrive, provided there is a sufficiency of warmth. It requires no care, and can be propagated by seeds or by planting.

CHEMISTRY IN CHINA.—The Chinese are beginning to adopt western chemical science, and a

factory has recently been erected for the manufacture of sulphuric acid on a large scale. Two well known chemical text-books—Malgutti's Elementary chemistry, and the Chemical analysis of Fresenius have also been translated into Chinese, with the help of a great number of new characters, and adopted in the imperial colleges. His excellency Tong Kiu Siug, the first minister, has taken the work under his immediate patronage, and written the preface for the first of these books.

AMMONIA.—More than fifty patents, it is said, have been taken out for the making of ammonia within the last two years, in England, America, Belgium, France Austria and Germany. Many of the schemes have been patented in all the countries at once. The patents apply to gas works, oil works, blast furnaces, alkali works, and sewage works. Ammonia seems to share with electricity the present attention of the patentee world.

LINOLEUM can be kept perfectly fresh and bright if, after washing, it is rubbed over with new milk which has been thoroughly skimmed, so as to remove all traces of cream. If any cream is left in the milk the surface remains sticky, and rapidly becomes soiled. The skin-milk forms, when dry, a smooth elastic varnish, which permanently protects the linoleum and assists it in resisting wear.

THE banana is probably the most productive food plant that grows. It is asserted that upwards of two tons of fruit can be produced from a single acre planted with bananas; and that the area that would be required to raise wheat enough to sustain one man would produce bananas sufficient to sustain more than 50 men.

BRICK VS. IRON.—An architect of New York, speaking of building material, says: "Under the rational order of things, brick will survive centuries without showing its age, but an iron structure, under the best of care, will begin to show the weight of years by the close of the first century."

ALUMINUM can be beaten out, either hot or cold, as perfectly as gold or silver, and can be rolled in the same way. Leaves as thin as those for gilding and silvering can be made of it, and it is easily drawn into wire. Its high cost prevents its use extensively in the arts.

GOOD HEALTH.

The Use of Salt.

We have received from a correspondent, says the London *Lancet*, a letter making some inquiries into the use of salt, and we are given to understand that, among other follies of the day, some indiscreet persons are objecting to the use of salt and proposing to do without it. Nothing could be more absurd. Common salt is the most widely distributed substance in the body; it exists in every fluid and every solid, and not only is it everywhere present, but in almost every part it constitutes the largest portion of the ash when any tissue is burned. In particular it is a constant constituent of the blood, and it maintains in it a proportion that is almost wholly independent of the quantity that is consumed with the food. The blood will take up so much and no more, however, much we may take with our food; and on the other hand, if none be given, the blood parts with its natural quantity slowly and reluctantly.

Under ordinary circumstances, a healthy man loses daily about twelve grains by one channel or the other, and if he is to maintain his health that quantity must be introduced. Salt is of immense importance in the processes unministering to the nutrition of the body, for not only is it the chief salt in the gastric juice and essential for the formation of bile, and may hence be reasonably regarded as of high value in digestion, but it is an important agent in promoting the processes of diffusion, and therefore of absorption. Direct experiment has shown that it promotes the decomposition of albumen in the body, acting probably by increasing the activity of the transmission of fluids from cell to cell. Nothing can demonstrate its value better than the fact that if albumen without salt is introduced into the intestines of an animal no portion of it is absorbed, while it all quickly disappears if salt be added.

If any further evidence were required it would be found in the powerful instinct which impels animals to obtain salt. Buffaloes will travel for miles to reach a "salt-lick," and the value of salt in improving the nutrition and the aspect of horses and cattle is well known to every farmer. The popular notion that the use of salt prevents the development of worms in the intestines has a foundation in fact, for salt is fatal to small thread-worms, and prevents their reproduction by improving the general tone and the character of the secretion of the alimentary canal. The conclusion, therefore, is obvious that salt, being wholesome, and indeed necessary, should be taken in moderate quantities, and that abstinence from it is likely to be injurious.

A DISCOVERY IN RELATION TO HYDROPHOBIA.—M. Pasteur recently made an interesting communication to the Paris Academy of Sciences in relation to canine madness. His experi-

ments had shown him that an injection in the region of the skull of the virus of rabies always produced the malady in an acute form, but that an injection in the veins only occasionally had acute results, being often followed by chronic affection only, without barking or ferocity. If a dog were inoculated with fragments of marrow or of nerve taken from a mad dog, the disease would be communicated. M. Pasteur further stated that he had rendered twenty dogs proof against the disease by inoculating them with other virus than the virus of rabies. Fowls and pigeons injected with the latter became affected, but soon recovered spontaneously. *London Standard.*

Strange Attitudes in Death.

Professor C. E. Brown-Sequard writes that at the battle of Williamsburg a United States Zouave was shot directly through the forehead as he was climbing over a low fence, and his body was found in the last attitude of life; one leg half over the fence, the body crouching backwards. One hand partially clinched and raised to the level of the forehead, presented the palm forward as if to ward off an approaching evil. A brakeman of a freight car on the Nashville and Chattanooga Railroad was instantaneously killed by a shot between the eyes, fired by a guerrilla. The murdered man was screwing down the brake at the moment of the shot. After death the body remained fixed, the arms rigidly extended on the wheel of the brake. The pipe which he had been smoking remained still clasped between his teeth. The conservation of the last attitude can take place in other circumstances than sudden death from wounds to the brain: the heart or the lungs, although an injury to a vital organ is the most frequent cause of that phenomenon. A detail of United States soldiers, foraging near Goldsboro, N. C., came suddenly upon a party of Southern cavalry dismounted. The latter immediately sprang to their saddles and, after a volley had been fired at them, they all but one rode away. That one was left standing with one foot in the stirrup, one hand, the left, grasping the bridle rein and mane of his horse, the right hand clinching the barrel of his carbine near the muzzle, the butt of the carbine resting on the ground. The man's head was turned over his right shoulder, apparently watching the approach of the attacking party. He was called upon to surrender, without response, and upon a near approach and examination he was found to be rigid in death, in the singular attitude described. Great difficulty was experienced in forcing the mane of the horse from his left hand and the carbine from his right. On the battlefield of Beaumont, near Sedan, in 1870, the dead body of a soldier was found half sitting, half lying on the ground, delicately holding a tin goblet between his thumb and forefinger and directing it toward an absent mouth. While in that position the poor man had been killed by a cannon ball, which had carried away the whole of his head and face except the lower jaw. The body and arms had been suddenly seized at the time of death by a stiffness which produced the persistence of the state in which they were when the head was cut off. Twenty-four hours had elapsed since the battle.

The Mobility of the Brain.

It has long been known that the brain in normal conditions undergoes certain rhythmical movements. The powerful vessels at its base cause the cerebral mass to rise and fall with each systole and diastole of the heart. The brain also rises slightly with each expiration, and sinks with inspiration. These phenomena are dependent, it is presumed, upon the presence of the cerebro-spinal fluid, since, when that is withdrawn, the movements cease.

M. Luys, in a paper recently read before the Academie de Medecine, states that the brain is subject to still other changes in position, dependent upon the attitude of the body. If a man is in the dorsal decubitus, or lies upon his side, or stands upon his head, the brain undergoes certain corresponding changes in position in obedience to the laws of gravity. The movements take place slowly, and the brain is five or six minutes in returning to its first position.

From these anatomical data M. Luys deduces some striking conclusions of practical interest. He explains, upon the theory of these gravitating movements, the symptoms of vertigo and faintness, which feeble persons experience when suddenly rising from a horizontal position. He asks if the pains of meningitis are not due to an interference with these normal movements. In cases of insanity he calls attention to the excitability and agitation which often come on when the patient lies down at night. As a practical points in mental hygiene, M. Luys advised against prolonged travel during most of the day, and urged the value of giving the brain the change produced by a horizontal position at night.—*The Medical Record.*

BLINDNESS is steadily decreasing in England, owing, it is considered, to the advance in surgical treatment of the eyes, and to the decline of such diseases as small-pox, etc., among children. For thirty years this affliction has gradually lessened, but within the last decade the improvement is specially noticeable and the last returns reckon some 22,832 blind persons—about one in every 1,138.

MINING SUMMARY.

The following is mostly condensed from journals, published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Inyo.

THE MODOC CON.—Inyo Independent, May 16: This company has 19 men at work at the present time. At the furnace there is on hand 729 tons of ore and at least 60 tons in the chute. Supt. Frank Fitzgerald has just let a contract to John Schober to burn 16,000 bushels of coal, and to cut 55 cords of wood. He has a force of 20 men, burning, chopping, etc. The wood is nearly all in and as soon as 6,000 bushels more of coal is delivered operations will commence, for a "50-day" run or more. As the coal will all be in by the 13th, everything will be ready to start on the 21st inst.

DEEP SPRING DISTRICT.—Mr. P. A. Chalfant came in from Cottonwood creek, Deep Spring district, Thursday last, to which place he will return again in two or three days. He informs us that the Greenly mill is about ready to start up, and that the prospects generally in that region appear to be particularly encouraging. Also that the Montezuma furnace material is now all on its new site at Antelope Springs, where it is to be re-erected immediately under Mr. Bray's superintendence.

Mono.

STANDARD CON.—Bodie Free Press, May 19: Employed during the week twelve miners and one watchman at \$4 per day. There has been a very marked decrease in the flow of surface water during the week. Will be able to resume milling some time next week. South drift No. 1 from south winze No. 2, from 385-foot level, has been run 12 ft; total length, 50 ft, showing 1½ ft of milling ore. North drift No. 3 from main west crosscut has been advanced 13 ft; total length, 141 ft, vein, 3 ft wide. South drift No. 4, from east crosscut No. 2, is in 105 ft; progress, 13 ft, showing 2 ft of vein.

BODIE CON.—Upraise No. 1, 800-foot level, has gained 15 ft. There is no improvement to note in the grade of the ore. Upraise No. 4, 300-foot level, has gained 11 ft; total height, 58 ft, with no change to report. Upraise from 770-foot level shaft level, has gained 6 ft; total, 54 ft. The ledge here is 3 ft wide, and shows some improvement. At the Bodie Con. mill there was crushed 150 tons of ore. This ore is from the 550 and 770-foot levels of the Lent shaft. At the Bodie Tunnel mill there were crushed 342 tons, mostly from the Vulcan vein. The average assay value of the pulp is \$26.31, and of the tailings, \$2.56.

BULWER CON.—Employed three men at \$4 per day. The south drift from the west crosscut No. 2, 500-foot level, has been run during the week 12 ft; total length, 240 ft, showing about 15 inches of vein in the face.

GOODSHAW.—The Goodshaw mine was closed down last week for the present. They contemplate making improvements and putting on a large force of men next month.

BODIE TUNNEL.—North drift, 200-foot level, the vein is 2 ft wide of free milling ore. At the expiration of the Bodie lease the Bodie Tunnel will continue running the same.

Nevada.

A RICH DISCOVERY.—Foothill Tidings, May 16: For several days a few Portuguese have been sinking on the croppings of a very large ledge in Pleasant Valley, on the south side of the road, a few hundred yards below Rapp's place. The shaft is down about 18 ft and the ledge is from 18 inches to two ft in thickness. Several hundred dollars have been taken from the quartz so far, and none of it has yet been crushed. The rock is exceedingly rich and seems to improve as depth is obtained. A gentleman who was there on Sunday says he saw the men pick about \$60 worth of gold out of the quartz with a pen-knife.

CON. PLANET DRIFT GRAVEL MINE.—A letter received yesterday from the foreman of the Planet states that the tunnel is progressing finely, the work being in slate which works well and stands without timbering. The cost per foot now is only about four dollars. The tunnel is large enough for a locomotive, and one will be ordered and ready by the time the channel is reached. This is one of the most valuable properties in California, and is managed in a way that insures justice to the small as well as the large stockholder.

THE MAGENTA MINE.—This morning the Magenta company started men to work on the drain tunnel. The tunnel will have to be run a distance of about 644 ft before it reaches the main shaft and the work will be in 8 hour shifts, and will be pushed forward as soon as possible.

PEABODY MINE.—The Peabody mine is now looking better than it has ever looked, and the owners have just cause to rejoice, for the prospects are indeed very fine. A recent crushing of ten loads of quartz from the Peabody gave a yield of \$24 per load. The ore now being taken out is very rich. That quality shown us to-day by Supt. Jas. Bennallack, will yield \$250 per load. There is a six-inch ledge where this rich ore came from. The shaft is now down 250 ft, and in another week a new station will be started. The company are employing ten men including trippers, and are cross-cutting. The ledge now being worked is the regular Peabody ledge and not the Rhodie Island Ravine ledge, the latter one having been lately run on by the company. To say the least, the prospect at the Peabody is very encouraging, and Mr. Bennallack says that he has no doubt but that there will be forty men at work there within one month. The shaft is 80 ft below the prospect level, and there is a drift of 400 ft underground.

Plumas.

HALLSTEAD MINE.—Phinas National, May 16: From Mr. J. S. Jaquith, who last week visited the Hallstead mine, we learn that nothing new is to be noted. The ledge still continues to justify the high expectations concerning it, and is widened both laterally and perpendicularly. The ore prospects well for the whole sixteen ft in width of the ledge. Some hard rock is found at the western end, but nothing to detract from the value of the mine.

MINING NOTES.—Work has been resumed at the Mills shaft. The Loring & Leavitt mine at Elizabethtown has been put in first-class shape, and the owners will start their new shaft on Monday next. The boys on Mill creek have got on to a good lead of black, rusty gold. They are getting fine prospects, as much as \$5 to a tub. The drifting was carried so near the bank of the creek that it caved on them and they will have about 100 ft of flume to put in before they can push along much. The Bell's Bar Company have decided to sink a new shaft not far from the old one; work will be commenced immediately. The Consigne Gold Mining Co. are in with their tunnel some 1,600 ft. They have recently run 32 ft in hard blasting rock, but the Supt., Charles Hanson, expects to soon get through it and has high hopes of the mine. He is having a new road made from the Bear Pen to the Company's mill that will materially improve the facilities of reaching the latter. Riverdale is running smoothly, with good prospects and pitching bedrock.

MCLLELLAN.—Greenville Bulletin, May 16: One of the most promising mining prospects around here is the McLellan owned by McIntyre and McIntosh. This was one of the first claims worked in the district, more than 20 years ago. Near the summit of the mountain, and at the surface of the ground, Henry C. Bidwell and John Waterworth. These parties made no effort to develop the mine after the surface ore was worked, and the claim was abandoned and remained untouched for many years. Recently it came into possession of the present owners, and these have already done a good deal to develop it. Three tunnels have been run at different elevations; No. 1 the ledge is opened 30 ft; No. 2 has yet to be run 80 ft before it will reach the ledge, and in No. 3 it is exposed for a distance of 500 ft. From the level of No. 1 a depth of fully a thousand ft of backs would be gained, and the existence of the ledge all of that depth is demonstrated. The mountain is exceedingly steep, the ledge runs at nearly right angles to the surface, and all the way up is found after running a short distance by tunnel. The ore has been prospected by experts again and again, samples being taken from all accessible points. The results in every case were satisfactory. The value of this claim is so clearly established that parties have offered the owners to build a mill for an interest in the mine but the offer has not yet been accepted. A most advantageous mill site is found just below the lower tunnel. Water power can be had from the Round valley reservoir, and the ground is thickly covered with choice mine timber. The McLellan could easily be developed into a valuable mining property.

A BIG FIND.—Sierra Tribune, May 15: J. P. Hall, who formerly resided in this county and was at one time manager of the Good Hope mine, from all accounts made a lucky find in the quartz line at Greenville, Plumas county, a couple of weeks ago. Since the early mining days of that district it was supposed that a rich ledge crossed near the head of Taft ravine. Thousands of dollars were expended by prospectors in hunting for the ledge, but it was not found, and the search was given up years ago. The Bulletin gives the following account of the discovery: "Mr. Hall had often heard the old miners speak of the rich rock found in the ravine, and when coming down the mountain last fall from the Ophir mine owned by him, looked over all the ground where the prospecting had been done. Some distance down the mountain he noticed several shallow holes from which the quartz had been thrown out. This led him to think that if the tunnel was in bedrock, the ledge must be between these holes, and it was. A couple of weeks ago he went to work in one of the holes mentioned, and after getting the snow shovelled out started to run a cut up the hill. Near the surface rich float-rock was found, and in a few hours he struck what he believes is the long sought ledge. At the point of discovery it is seven ft wide. Surveyor Higbie has no doubt that it is a permanent ledge, and the one so much prospecting was done to find. Several old miners have examined the ledge and all are firm in the same belief; several have also made proposals to buy interests in the claim, but Mr. Hall has refused to sell till he shall do some more development. He has means to prospect the claim thoroughly."

Sierra.

A GOOD STRIKE AT THE HOMESTEAD.—Sierra Tribune, May 15: A strike was made at the Homestead quartz mine some time ago that has not been mentioned in the newspapers before. As our readers are aware this mine is located on Rock creek only a quarter of a mile or so distant from the Ruby gravel claim. Stephen Spencer and others purchased the mine a couple of years or more ago from an old prospector, who goes by the name of "Quartz" Johnson, and proceeded to build a ten-stamp mill, run a tunnel and otherwise develop the property. The tunnel run tapped the ledge 60 ft below the surface and a shaft that had been sunk by the former owner. Last season Mr. Spencer found indications of gravel and came to the conclusion that a channel coursed through the ground. This led to the starting of another tunnel in the fall, down by the mill. Work was carried on in that quarter all winter, and after running some 500 ft a four-foot vein of quartz was crossed. An east drift was immediately started along the vein and at this writing has been run 30 ft. At this point, which is 200 ft below the old workings, the ledge is even stronger than above, showing some fine ore. The party who gave us this information had a couple of pieces of rock that came out of the new tunnel and they were as rich specimens of gold bearing quartz as out reportorial eyes have feasted upon for some time. A clean-up was recently made in the mill after a couple of months run on ore taken from the upper stopes. The yield was very satisfactory. There is now every evidence that the Homestead will soon become a leading quartz mine.

ENCOURAGING PROSPECTS.—J. T. Bradbury has struck ore in the Spohm ledge that prospects first-rate in free gold. This claim is located on Kanaka creek, something over a mile below the Rainbow mine. A number of years ago the ledge was worked quite extensively and yielded quite an amount of very rich ore. For a number of months past "Brad" has been engaged in running ahead the main tunnel and is now making a connection between the old stopes for the purpose of getting better air.

WORK TO START UP.—T. Ellis, who is one of the owners in the Arizona mine, was over from Forest City this week and informed us that the Company would resume work in the tunnel next month. It will be run by contract. The tunnel is now in slate

rock having been run 700 ft. The Company hope to strike gravel in three or four hundred ft further ahead.

PIKE CITY.—Mountain Messenger: The Alaska shaft is full of water. Two tanks are fixed for bailing, 50 inches coming out. Steam pumps will be put in as soon as water is sufficiently lowered. Two boilers have been set. Two more are being put in place—250 horse power, more than had previous to the fire. J. H. Bates one of the heaviest stockholders, expected to soon arrive from the East, when the development of the mine will be resumed. Supt. Davis still in charge of affairs.

ALLEGHANY.—Joe Stephens, of Sierra City, is expected to arrive here this week to put four men to work on Hauber's ledge in the interest of Supt. Deidesheimer, of Sierra City. The croppings of this ledge are very rich. Doc. Bowers is stopping at the Golden Gate quartz mine; W. N. Hooper has the property in charge. The main tunnel of the Rainbow is in over 1,100 ft, to tap the ledge about 400 ft below the old works, 2,400 ft in all to run, 45 to 50 ft to make a week, 16 men employed. One air compressor and two Burleigh drills used. Ledge is expected to be struck by the 1st of Nov., and the mill will probably be running by next spring. W. F. Hanley is now Supt.

Shasta.

BUCKEY.—Cor. Redding Independent, May 6: Miners appear to be doing fairly well this season. Messrs. Wilcox and Cochran have been hunting "pockets" with good success. They have taken out over \$800 worth of gold within two weeks, with still more prospects ahead of them.

SILVER.—Shasta Courier, May 16: James Brindard, this week, brought in a sample of silver ore from a ledge discovered by Lowery, between the Gage place and head of a gulch, which puts into Olney creek, which assays here show \$84 per ton. That neighborhood is rich in minerals. The Churntown and Buckeye miners never have, nor now propose to allow Chinamen to work the mines of those districts, and all attempts to introduce the Mongolians there fails.

Siskiyou.

NOTES.—Yreka Union, May 16: From Mr. Brown we learn that they recently crushed 18 tons of rock from the Bonanza which yielded nearly \$300. Miller & Mallow crushed 25 tons of rock from their mine which went \$72 to the ton. Sorenson has out about 40 tons of good rock, which will be crushed at Vacant's Mill. Mr. John Steward has out about 35 or 40 tons of rock which will go \$20 to the ton. All of the placer miners are at work with good prospects. At Hamburg Bar quite a number are making preparations to go to work in the river as soon as the water goes down. Mr. W. Kittelwood will go into the Klamath below the mouth of Scott river as soon as the high waters recede.

Trinity.

DEADWOOD DOINGS.—Journal, May 16: Quartz mining in Deadwood District is fast becoming one of the leading industries of the county. McDonald & Franck are now putting up a five-stamp mill and R. N. Davidson has just received a cannon-ball mill which will be put in operation without delay. All the mines now being worked there are reported as doing well, and the gold yield from that District will materially increase the produce of the county for the current year.

Ventura.

EXCITEMENT ON THE PIRU.—Ventura Democrat, May 15: A scene very familiar to our eyes greeted us Tuesday morning in front of Corey's store, Main street. It was none other than an excited crowd surrounding a brace of solemn visaged burros, packed with shovels, picks, pans, blankets, grub and all the usual paraphernalia pertaining to a modern mining outfit. Upon inquiry we learn that Messrs. Snuffin and Castano, citizens of the Santa Paula section, had brought to town the day previous several specimens of fine looking silver ore which were exhibited to some of our energetic and impulsive citizens, hence the commotion. Messrs. Wm. Williams and Witherell had started for the scene of discovery the evening before, and Messrs. Hall, Vickers and Harley were with loaded donkeys, ready to take the road for the same destination. If the favorable reports are confirmed by those gentlemen, the Piru country will doubtless witness a rush for its hidden treasures. The ore was found on the summit and at the eastern extremity of Pine mountain, between the Piru and the Sespe. The ledge from which the specimens were obtained is said to be from six to ten ft wide and traceable by its croppings for a mile or more. The existence of the precious metal in the Piru mountains has long been known and it seems to be an undoubted fact that in this locality, instead of Sutter's mill, was found the first gold discovered in California and that Francisco Lopez, is entitled to the distinction of first discovery, erroneously conferred upon Marshal. Lopez learned of the existence of gold there, from the San Fernando Indians and utilized the information thus obtained by digging it and selling his nuggets to Los Angeles traders as early as 1837.

NEVADA.

Washoe District.

COMBINATION.—Enterprise, May 16: The shaft has reached the 2900 level, where they are putting in a pump tank and making preparations to lower the Cornish pump to said point. At this depth a station will be made and a drift started west. This drift will drain all the ground above the 2900 level.

BEST AND BELCHER.—Good progress is making in the two east crosscuts on the 1200 level, and the formation is of a promising character. On the 2700 level the north drift still continues in material that shows some metal. The rock has a very lively and "kindly" appearance.

SIERRA NEVADA.—The northeast drift has been advanced about 20 ft. It has passed into a new and peculiar formation which promises well. The diamond drill is still running in west crosscut No. 2. It shows that there is very little water in that direction.

UTAH.—The southeast drift on the 1950 level has been extended 35 ft, and continues in vein material similar to that found in the north drift on the same level; that is, a mixture of quartz and porphyry.

OPHR.—Are still finding some low grade ore in the filling of the old drifts and other openings on the 250 level. The ore extracted is being worked at the

Morgan mill on the Carson river.

YELLOW JACKET.—The old upper levels continue to yield well in the usual character of ore, keeping the river mills at work. The prospecting operations disclose low grade ore at several points.

MEXICAN.—Have made 11 ft in the winze below the 3000 level this week. The ground is perfectly dry. At the present rate of sinking the winze will soon reach the 3200 level.

SAVAGE.—Are constructing a stone bulkhead in the north drift on the 2600 level. This bulkhead will be placed at a point about 40 ft back from the face of the drift.

GOULD AND CURRY.—Are waiting for the water to drain out of the southeast drift on the 2700 level. The water is decreasing, but it still make the drift very hot.

CALIFORNIA.—The usual progress is making in the east drift on the 2900. The repairs to the C. and C. joint shaft are still continued.

HALE AND NORCROSS.—Are taking out ore from the 200 level through the old F street tunnel. Work on the 2800 has not yet been resumed.

BELCHER.—All work in the old upper levels is going on about as usual. Ore enough being extracted to keep the mills in operation.

CON. VIRGINIA.—The east drift on the 2900 level has been extended about 30 ft. Are still repairing the C. and C. joint shaft.

UNION CON.—West crosscut No. 4, recently started is out about eight ft. As yet it shows no change of formation.

ALTA.—Are still drilling west on the 2150 level, and making repairs to both the east and the west drifts.

ANDES.—A considerable amount of prospecting is being done and some low grade ore developed.

UNION SHAFT.—Are still repairing the drain drift connecting with the Suro tunnel on the 1600.

CROWN POINT.—The usual amount of ore is being extracted, and the mills on the Carson river are kept running to their full capacity.

Arabia District.

AT WORK.—Silver State, May 16: The mining outlook in the southwestern part of the county is brighter than it has been for some time past. Deputy Assessor Buckner says there are eight or ten miners at work on a mine in Arabia district, west of Oreama, taking out base metal ore, which are being shipped to Fairbairn to be smelted. At the Humboldt Queen mine, near Rye Patch, several miners are employed extracting ore, the richest of which is being shipped to Denver for reduction.

Belmont District.

DOUBLING CAPACITY.—Belmont Courier, May 17: Superintendent N. C. Fassett informs us that the Belmont Mining Company has decided to enlarge the leaching works to double the present capacity, and that the additional tanks, etc., have been purchased and will soon arrive here. Men are now at work on the building and it will not be long before the works are ready for use. A long and profitable run is confidently expected. The Belmont mine is looking better and better as the work of development advances. The ore extracted from the 200 foot level south carries rich chloride and black metal. The prospects are certainly good.

Battle Mountain District.

COPPER.—Battle Mountain Messenger: The Duchess Smelting Co. have purchased the Copper Queen mine, situated in Old Battle Mountain mining district. From W. H. Taber, President of the company, and A. J. Kallston, their business manager, we learn that a small force of men will be put to work on the Copper Queen next week to test its merits, and if it prospects favorably, as is anticipated, a new 60-ton copper furnace will be erected some place in the vicinity of the mine.

Central District.

RED ORE.—Silver State, May 16: In Central district several miners are at work, and at least two mines—the Railroad and Locomotive—are looking well.

Eureka District.

GEDDES.—Eureka Sentinel, May 16: Supt. R. D. Clark, states that, under instructions from his company, he will resume work in the Geddes mine immediately. For the present only seven or eight will be put on, who will be employed to do dead work. As soon as the roads improve sufficiently, a large supply of wood and salt will be hauled in for use at the reduction works. After some preliminary work is done, and the way cleared for thorough exploration and ore extraction, a large force will be put into the mine. When the leaching works start up, it will be to run a good long while without stopping, for it is the plan to start up with a good ore reserve, and to work the mine for everything that is in it. And, as everybody is convinced, it is a big mine.

Jefferson District.

RESUMED WORK.—Belmont Courier, May 17: We learn from J. J. Hayden that the Harrison Brothers have resumed work on their mining property at Jefferson and that they are extracting good paying ore. The little mill is now running on ore from their mine. Mr. Hayden also informs us that Charles Kanroth is running his leaching works on ore from the Jefferson Carbonate mine. The ore is of an excellent quality. Work on the Cora D. mine, at Jefferson, is being prosecuted with energy, and this property is looking well. We have seen several specimens of ore recently extracted from this mine; they all carry rich chloride. Free gold is also plainly visible in this ore.

Mount Cory District.

LOOKING UP.—Walker Lake Bulletin, May 14: As has been often predicted, mining matters are looking up, and the camp will soon be active. Some prominent Hawthorne capitalists run up here last week, looking at the North Star mine. Although the camp is looking up, there are plenty of men here, and men out of employment are not needed. The Coeur d'Alene excitement has died out. Coryville people will do their stampeding around among their home hills. The road from the mine to the mill is in excellent order, and the ore teams make their trips with the regularity of railroad trains.

Spring Valley District

OPENING A LEAD.—Silver State, May 16: At Spring Valley L. F. Dunn is opening up a lead

which promises to rank among the best in the county. Deputy Sheriff Anderson, who was down in that vicinity a few days ago, says the lead is very large and carries from four to six ft of ore.

Star District.

ORE.—Silver State, May 16: In Star district, the Grizzly mine is being worked, and is producing considerable ore that works from \$500 to \$1,000 per ton.

Ward District

ORE.—Ward Reflex, May 16: O. M. Converse, who has the contract, commenced hauling ore to the Monitor mill Sunday. The Argus teams will commence hauling in a day or two.

ARIZONA.

Mohave.

DIFFERENT DISTRICTS.—Mohave County *Miner*, May 16: Men are working on the Constellation mine, near Cerbat. Superintendent Moses is pushing work on the Starke and Ewing mine day and night. Among the numerous transfers of mining property recently made we notice the sale of a one-half interest in the Prince George mine at Stockton Hill from Caldwell Wright to T. J. Christie. The sale was made May 6th for the consideration of \$8,000. Mr. Christie has already put four men to work on the mine for the purpose of extracting some of the high-grade ore for which the mine is noted and of which there is a large quantity now in sight. Goin's pack train is at work in Maynard district. Work has commenced on the Deen mine at Wallapai mountain. Four men have been put on as a starter but double that number will soon be employed. Frank Hamilton has recently shipped about 3 tons of very high grade ore from the Mariposa mines at Wallapai mountain. He is now working on the Mississippi, an adjoining and equally valuable mine. Messrs. Little and Colman, who have been working on the Wallapai Chief mine in Maynard district, have suspended operations for a time. W. Richards, J. Corin, Pemberton and D. Parks, are getting out lots of gold ore from the American Flag mine. Woods' pack train will commence taking the ore from this mine to the Kingman sampling works next week. Chas. Roe, of the firm of Roe Bros., B. J. Elliott and J. F. Luthy have leased the five-stamp mill at Cerbat, belonging to the Arizona Northern Mining Company, for one year and have already commenced to put it in running order. They propose to work custom ore at reasonable rates. J. M. Quine has three men at work on the Hunkidori, near the Lone Star mine. In sinking a 30 foot shaft on the vein he has accumulated several tons of fine-looking ore, which goes from 10 to 15 ounces in gold to the ton. The ore streak is about ten inches in width. Good miners are greatly needed in the Wallapai district. It costs about one-half what it did two or three years ago to live in Mohave county, and miners' wages are still \$4 per day, and yet good miners are scarce. Frazer McCleod has sold the Storm Cloud mine on Potts' mountain, Owen district, to N. W. Clark and J. K. Maddock. Yeacham and Siebrecht have sold 750 feet of the New Year, Eagle and Orient claims to the Ferguson boys for \$750. These are gold ledges in the Gold Basin district.

BONANZA MINES.—Quijota Prospector, May 16: Owing to the absence of the superintendent at Tucson during a portion of the week, we are unable to get our usual complete reports of work on the mines. Tunnel No. 1 is 176 ft deep in softer ground. Crocker tunnel is in 174 ft and looks exceedingly favorable, the winze is being pushed forward as fast as possible. The Peer tunnel is about 160 ft deep, making great progress in softer ground. The well borers have finished their work. The company consider they have ample water for all purposes.

THE SOUTH QUIJOTA RANGE.—The north end of the south Quijota range lies about seven miles south of Quijota by a good wagon road. In a direct air line it would probably measure about 4½ miles. This range of mountains has attracted more or less attention for the past six months, owing to the fact that some rich ledges of black sulphure ore have been discovered there. A few days ago a Prospector representative, in company with C. L. Tisdale, visited the northern end of that mountain, for the purpose of prospecting it thoroughly, and after three days of hard toil failed to discover even a trace of anything mineralized. The north end of the range is a burnt up malpais, which, as every prospector knows, never carries mineral. A little range of foot hills that start to the west of Ben Nevis, running in a northerly and southerly direction, has the same character of formation as the above mentioned mountains. Owing to the scarcity of water in the south end of the Quijotas, that section was not visited.

OLD DOMINION COMPANY.—*Globe Chronicle*, May 16: One day this week—the 15th—two furnaces of the Old Dominion Co. turned out 32,860 pounds of copper. This is the largest run ever made anywhere by furnaces of only 30 tons capacity. The quality of the ore now being taken out of the Old Globe mine—and there is an enormous quantity of it in sight—is of such a high grade, and so easily smelted, that it is confidently expected that the output for this month will be the largest ever made by the company. The supply of coke keeps up, about 100 tons having passed through the town this week. As near as we could calculate we judge that the company shipped about 150 tons of bullion this week. A new 9x15 rock crusher has arrived and is being put in place; also a large steam pump for forcing water from the furnaces to the mines, a distance of about half a mile. The two furnaces now in operation require about 6,000 gallons of water daily. Heretofore this has, after performing its mission, been wasted; now the steam pump will force it into tanks erected for that purpose at the mine, and it will be used for the operation of the hoisting works and the diamond drill.

GREEN VALLEY.—We learn that there is a new quartz mill going into this valley, which will make the second one there. The rich developments made in this quarter in gold is drawing the attention of careful and prudent miners, and it promises to be one of the richest gold fields in Arizona. The new mill is at Winslow, in transit to Green valley, and is of ten-stamp capacity. We also understand that preparations are being made to build a railroad through the timber belt from Flagstaff to the Rim Rock. We are unadvised if this contemplated road is part of the Mineral Belt, or whether it is simply an enterprise of parties desiring to reach the fine timber for lumber purposes.

COLORADO.

NOTES.—*Georgetown Courier*, May 13: The lessees on the Pay Rock are said to be doing splendidly. A recent run of ore from the Pelican Dives gave 300 ozs. silver per ton. One hundred and twenty-five men are employed on the Freeland mine and smelter. Husted & Co., who are driving a tunnel on the Windsor lode, at Empire are in 90 ft. They have a good streak of scattered ore. The snow on the mountains is still preventing miners from doing the usual amount of work. Many idle properties at Empire and Dumont are to be started up this season, and both of these camps promise to be lively. Sixty-four tons and 644 pounds, net, were shipped from the Mendota mine last month. The total value of the same was \$4,408.83. Recent mill runs of ore from the Shively mine went 600 and 900 ozs. silver per ton. Quite extensive work will be done on this mine during the coming season. The recent strike in the Summit mine holds out well, while the ore increases in richness. A great deal of ore is being opened up, which runs very high. Very encouraging reports come to us from the Coin lode, on Brown mountain. In the slope above the lower level, westerly, a fair streak of ore has been encountered of which a mill-run of one ton was had last week, running, 1st class, 477, and class, 152 ounces silver per ton. Exceedingly rich gold ore was struck in the Centennial mine, within the limits of Georgetown, on last Saturday. A fine streak of ore was opened up at quite a depth an assay from which returned as high as 16 ounces gold 63 ounces silver per ton. An assay on ore from another portion of the mine went 428 ounces silver. The Vulcan mine, on Republican mountain, is working a force of 30 men. It is owned by Meyers Bros. and Pollard. On the Meyers lease, west of the main level, an ore streak ranging from one to eight inches in width, averages, coin value, 400 ounces silver per ton.

IDAHO.

CARBON CENTER.—*Coeur d'Alene Pioneer*, May 16: The new camp of Carbon Center is located at the head of Beaver creek—seven miles southeast of Beaver city. It is in the center of a flat basin which is fringed by high mountains. The site is a beautiful one, and from the developments made in the surrounding hills, Carbon promises to become a camp of no little importance. A good trail connects Carbon with Beaver, and there is good feed along the way. Quite a number of houses are already up, and building is progressing as fast as material can be procured. A large hotel is now in course of construction. The mines about Carbon are distinctively base, and there is no question but that they are on the galena belt passing by the head of Granite creek and over on to Butte creek. The ore about Carbon is mainly argenteriferous galena of good grade, but red carbonate has likewise been found. Every variety of galena is represented, and the ore has a general appearance of existing in a good, solid formation. Specimens brought in last Tuesday show black sulphurets, ruby and galena. The principal locations are the Virginia, Sunset, President and Rainbow. On the Virginia fifteen men are at work, and supplies are being packed to the mine. The vein is over seven feet wide, over half of which is solid metal. The Sunset is a strong vein of galena, but the snow on the location has retarded operations until the present time. It promises to be one of the banner mines of the camp. The President is a five-foot vein of carbonate and galena, which assays \$300 per ton. The Rainbow is mostly carbonate ore of good grade, but work on it has only just begun.

THE PROSPECTS.—*Coeur d'Alene Pioneer*, May 16: We may say without fear of contradiction, that for the amount of development, the prospects of the Coeur d'Alene country was never equaled by any other camp in the United States. The quartz recently discovered on Reader gulch is practically inexhaustible. There are thousands of tons above the grass-roots, and every ounce of it contains pay. We have an inexhaustible supply of fuel and water, so that ore can be worked cheaper than elsewhere. There is every reason to believe that each stamp will yield a greater profit here than in the Black Hills, and yield it for a longer time. We might say without exaggeration that the mountains are pay quartz, in much of which gold can be plainly seen. There will be more stamps in the Coeur d'Alene within five years than in the rest of the Union.

THE GALENA BELT.—We have in previous issues called attention to the fact that the discoveries of base ores in the Coeur d'Alene country is worthy of a share of the attention now bestowed on the gold interests. It is certain that galena and carbonate ores exist in this range in large quantities, and that it is of a paying grade. The mines are being developed rapidly, and we believe that they will ultimately be proven to be on one of the richest and most extensive base metal belts ever discovered. There is about Carbon, at the head of Beaver creek, extensive bodies of rich argenteriferous galena, which lay in well-defined ledges and in a steady formation. The series of mines extend northwest, and can be traced on to the head of Granite creek—a tributary of Pritchard. If we follow the flow of the belt we strike Butte creek, upon which good galena has been found. The character of the ore is so similar that it is reasonably certain it is the outcroppings of an extensive galena deposit which underlays that entire strip of country. The trend of the belt would cause it to cross by the heads of both forks of Eagle creek, and on to the sources of the north fork of the Coeur d'Alene river. We venture to predict that rich galena will be found in these localities, and in the end the mining of the base ores here will be as important a branch of the mining industry as the development of the gold interests are now.

ITEMS.—*Coeur d'Alene Pioneer*, May 16: Every side gulch where bedrock has reached contains good pay. The total output of Dream gulch to date is nearly \$12,000. The ditch from Alder creek is being dug. Work on the Mother Lode will be begun just as soon as the high water will permit. A tunnel will be run in on the ledge. The Lehi shaft is down 60 ft, and the ore body shows as well as ever. Ten men are still at work, and considerable ore is on the dump. The hills between Eagle creek and the North Fork contain extensive gravel deposits which will pay to hydraulic. The most extensive hydraulic diggings on the continent are right about us. The Star lode, within a stone's throw of Raven, is looming up as a big mine. The vein is of unknown

extent, but enough is in sight to warrant the Badger State Mill Co. in putting in a stamp-mill. There is no longer any doubt that one of the main channels of Pritchard creek has been tapped by the drain-ditch on the Butte claim. The gold is the coarsest yet found on the creek, and meets the fullest expectations of those interested in this development. The Margaret lode on the west fork of Eagle creek is opening up beyond the most sanguine expectations. The ore is of a peculiar nature, being in the transitory state between the base and free-milling varieties. The Margaret is full 15 ft in width, and averages clear across \$30 per ton. Development work is still progressing, but the present month must see its close. With the advent of the coming month the results of the labor bestowed in preparing the many claims for sluicing will be apparent. Those who have been sluicing on low bedrock during the past week have been compelled to move up. The warm weather has swollen the creeks to double their former volumes, and several tail drains have been carried off by the high water.

COEUR D'ALENE.—*Idaho Statesman*, May 16: The excitement with regard to the Coeur d'Alene mines seems to be quieting of late. Hundreds are still going in that direction from all quarters, but the hope of realizing "big strikes" in a short time is not so strong as it was during the winter when the deep snow covered the country and everything was left to the imagination. That there are some good mines in that region there is no reasonable ground for doubting, and it is quite possible that the country will prove worthy of occupation. Most of the adverse things that have been said have been inspired by the sensitive jealousy of the older mining camps through a fear of losing a portion of their local population. This, however, has had but slight effect in checking the onward march of the prospector, who will be always ready to try his fortune in a newly-discovered camp. The country in which the mines are located is large enough to furnish an abundant field for the gold-seeker, with as good chances of success as elsewhere.

PROSPECTING AT WOOD RIVER.—*Ketchum Keystone*, May 16: Although the snow has not yet fairly left the north hill sides, there are many prospectors going into the hills, and accounts of new and rich discoveries begin to reach us. It is not unreasonable to suppose that the prospecting season of 1884 will do more towards the development of Wood River's vast hidden mineral resources than all of her previous history has done. The reputation gained abroad for this country is very great and encouraging, and the number of immigrants already arriving daily indicates a very great influx. The more inhabitants we have the more prospectors, and, consequently, the more probable development of our mineral wealth. It is safe to say that were the number of prospectors now in the Coeur d'Alene region to invest Wood River, the world would be astonished by our wonderful developments and great riches. It is an old and erroneous custom that leads people to estimate the mineral worth of a country by its known discoveries and operations without any consideration whatever of its population. Wood River, but very sparsely prospected heretofore, bids fair to experience a moderate searching this year and we venture to assert that its importance as a silver mining region will be increased 100 per cent in the next six months. Lodes are being discovered everywhere now where heretofore it was thought nothing could exist and prospectors passed by in contempt. But the art of searching exclusively for croppings has passed away and the more scientific mineral seekers perplex the community by taking a spot of peculiar contour or a gopher hole for the starting.

A RICH STRIKE ON EAST FORK.—The news came through reliable miners from East Fork of Wood River yesterday that Messrs. Dunkey and Hillebrand have struck a rich blind ledge about half a mile from the North Star mine in line with that ledge and six miles due east of Ketchum. The ground there has been carefully prospected heretofore, but the lucky discoverers made their strike from very small pieces of float traced to a gopher hole, where operations were begun. They have cut into the hill a distance of about 20 ft and fine the surface ground full of large chunks of high grade galena. It is in a black slate formation and supposed to be but the break over of a large ledge that will very probably be encountered at the contact of this slate with a porphyry formation about 50 ft distant from the discovery.

THE SNAKE RIVER PLACERS.—*Idaho Statesman*, May 16: Mr. Cheesbro, who was largely interested until recently in placer mining on Snake river, has sold his interests to a company of Rhode Island capitalists, who will work these mines on an extensive scale. The company intends to build a dam across Snake river at a point some nine miles above Walter's ferry and construct ditches on both sides of the river. The mining ground which Mr. Cheesbro sold lies on the south side of the river just below the Silver City stage road and near the ferry; but the ditches to be constructed will cover good mining ground on each side of the river from their initial points to the ferry and for several miles below. Mr. Cheesbro informs us that the method now being adopted for saving the fine gold in these placers is to abandon the use of flates and quicksilver and leave the gold with the black sand. This is done by the usual process of washing and the use of concentrators. The black sand, thus concentrated, holds every particle of the gold and will average for most of the claims on the river about \$1,000 per ton. In this form, the product of the mines will be shipped to Omaha for reduction, where the black sand, which is nearly pure iron, is in great demand as a flux for the working of silver and lead ores. All the processes heretofore tried for separating the fine gold from the black sand in the working of the mines have proved but partially successful, and material improvements in these processes go on so slowly that the practical conclusion has been reached of leaving the two together for the process of reduction. This is believed to be the best plan of working the mines at present. When this method is generally adopted, the yield of the mines will be very much increased as they can be readily and cheaply worked wherever water can be got on the bars.

MONTANA.

THE GRANITE MOUNTAIN MINE.—*Cor. Butte Miner*, May 16: From reliable sources I learn that the daily work of development continues as usual—satisfactorily to those most directly interested and

very flattering to the future permanence of the mine. The dumps fairly overflow with high grade ore, and the quantity in sight in the stopes appears to be almost inexhaustible. As yet the company have taken no steps to build a mill, or to reduce their ores in those here, already to run, but idle from necessity. The Algonquin mill, it is supposed, until quite recently, would crush ore from this mine. A large amount of wood has been hauled to other works, under orders from the resident superintendent, seemingly for that purpose, but as nothing is being done towards getting the machinery in readiness, I infer that legal difficulties, of recent date, must have interfered with the arrangements that rumor had happily consummated between the St. Louis and Philadelphia companies. I am firmly of the belief, however, that whenever the Granite mine will show a million tons of \$500 rock in sight, that the poverty stricken gentleman who own it, will feel justified in erecting a five stamp water mill without losing any sleep over the expense of reduction or construction. So we of the Flint creek mining district patiently await the future.

SAN FRANCISCO CON.—The tunnel header stands in four ft of good milling rock. From the hard and compact nature of the country, the present depth of 110 ft vertical, from the surface, together with two smooth and perfect walls, I am inclined to believe that the vein will continue to improve as the level advances eastward. Certainly the mine never looked so well as at present.

NEW MEXICO.

GENERAL NOTES.—*Silver City Enterprise*, May 16: The Black Hawk mining company shipped three cars of high grade ore last week. The last shipment of ore from the Cooney mine averaged \$400 per ton. That is good enough. The Sherman mining company have agreed to furnish thirty tons of ore per day for the first month's run of the new concentrator of this city. The Organ smelter "blew in" a short time since and is said to be working very successfully and giving entire satisfaction to all parties concerned. An item has been going the rounds of the territorial press to the effect that the Bremen mine had been sold to Gustav Billing for \$500,000. Mr. Bremen denies all knowledge of the affair; hence the rumor must be false. Pat Bradley, a musician formerly of this city, but who is at present residing in El Paso, purchased the interest of Fitzgerald in the Penrose Bonanza and other mines at Fleming. Mr. Bradley will commence development upon these claims as soon as the necessary arrangements can be made. The Hillsboro stamp mill is running night and day on the Oro Fino and O'Kelley gold ore. Two hundred dollars rent is paid for the use of the mill which is obtained from the mine six or seven miles, and a loss on the mineral in the rock through a failure to work it closely is considerable, yet the owners of the property are making money and are happy. J. C. Woodward has erected a small furnace smelter at his place at the north end of town, in which he intends treating his carbonate ore from the Hanover claim, of which mention has been previously made in these columns. The smelter was tested last week and was found to work admirably as the ore is self-fluxing. The concentrator is running nicely now, is doing good work and giving perfect satisfaction. The St. Cloud ore was tried this week, and proved to be very easy of separation. The mill has need of a finer meshed screen and has one en route hither. When it comes the tailings which are not now as clean as might be desired, will be put through the mill again. What may prove an extensive strike was made last week upon one of Bremen's mines in Chloride Flat. A miner while shoveling over an old dump on the Back Bone claim ran his shovel a few inches under ground and found upon withdrawing it some very rich looking ore different in character from that of the dump. Digging was continued and the foreman notified of the important find, as it proved to be. The ore was tested by two different assays, one running \$1,880 and the other \$2,541. Fourteen tons were taken out and sacked for shipment in a very short time, and to all appearances there are no signs of a pinch in the ore body. Reports from Fleming hitherto have been somewhat contradictory as to the existence of coal in paying quantities, and in fact it might be justly urged by those totally unacquainted with the surroundings of that promising camp, that geologically considered, if it existed at all, it is the result of a displacement. The Enterprise having in view only the dissemination of reliable information, after careful inquiry, is not only pleased but gratified to make the announcement that the existence of coal in paying quantities and—for a prospect—of excellent quality has been found. The owners of this valuable find, Smith & Co., are developing as rapidly as possible, and the next twenty days will show up that which is destined in the near future to be one of the leading industries of this and the regions adjacent to Grant county. As developments progress our readers will be duly informed and in due time we are promised a descriptive article of the entire Fleming region.

UTAH.

REVIEW.—*Salt Lake Tribune*, May 16: The mining record for the week, as far as movement of the metals is concerned, has been merely nominal, the receipts being the least of any week for the year, with one exception. The receipts in this city of bullion for the week ending May 14th, inclusive, were \$48,750; of ore, \$2,850; total, \$51,600. The receipts of bullion of the week before were \$75,894.39. The shipment report is withheld for the present by the dealers. The Horn Silver shipped two cars a day regularly, amounting to 12 for the week, \$36,000. Total shipment to date, \$765,000. The Ontario made no shipments during the week, the mill being shut down for cleanup and repairs. Great interest is being taken in the opening of the new gold level; if it shall prove as much of an improvement over the 800 as the new levels have averaged, it will give a noble future to the mine. The product of the Hanauer smelter for the week was six cars of bullion, \$12,150. The bad roads in the hills are a very serious hindrance to the mining activity. In consequence of this nothing was heard from the Crescent during the week, and the Stormont also failed to show up. The roads will not improve rapidly, either, for the snows are so deep that they will supply plenty of mud for some weeks.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved forms. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. Tide latter size furnished J. B. Haggin, or Olan and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Oils Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

WORTHINGTON MINE PUMP.

ALEXANDER L. HOLLEY, being duly sworn, says: I am by profession a civil and mechanical engineer. I have been especially employed during the last ten years constructing and managing works for the manufacture of Bessemer steel. I am now Consulting Engineer to the Bessemer Steel Works of Troy, the Cambria Iron Works, the Bethlehem Iron Works, the North Chicago Rolling Mills, the Joliet Iron and Steel Works, and the Edgar Thomas Steel Works. In all Bessemer Works the hydraulic machinery is the most expensive and the HARDEST WORKED part of the plant. Any delay or serious fluctuation in its operation is fatal to the commercial success of the Bessemer process. After extensive acquaintance with the WORTHINGTON ENGINES, and with all such other forms of pumping engines as have been applied to the purposes required, I have adopted it exclusively, and to my knowledge it is adopted in every Bessemer works running or building in America. I have also, for the same reasons, adopted the WORTHINGTON PUMPS for feeding boilers.

Will CONTRACT TO RAISE ANY REQUIRED HEIGHT SINGLE LIFT with our NEW PATENT MINE PUMP. Recent practical tests in Deep Mines of Mexico demonstrate this to be the BEST MINING PUMP extant. The largest stock of PUMPS for all purposes west of New York at our

BRANCH HOUSE, 30 and 32 First St., S. F.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

PEN-HOLDER.—Stephen A. Holman, Spencer-ville, Nevada Co., Cal. No. 298,090. Dated May 6, 1884. This consists in a new and useful pen-holder having a slotted stock, in which is pivoted a strip or bar, one end of which acts as a rest for the index-finger, and the other for the thumb, the whole bar serving to hold the stock at any proper inclination. Upon the stock is fitted a slotted sliding sleeve, having pivoted to it a link, the other end of which is pivoted to the bar. By the movement of the sleeve to enclose and guard the pen-point the pivoted bar is drawn into the slotted stock, and by its movements to uncover the points the bar is forced out again to act as a rest and support. The object of the invention is to provide a pen-holder specially adapted for beginners, which by its construction will compel its proper handling and use and permit an easy and comfortable grasp, and which may, when not in use, be closed up out of the way.

TOBACCO SWEATER.—George Brownstein, S. F. No. 297,668. Dated April 29, 1884. This invention relates to that class of tobacco curing or treating machines known as "tobacco sweaters," and more particularly to that subclass in which the tobacco is contained within a close, steam-tight and water-tight vessel, which is surrounded by a steam or water jacket. In machines or devices of this class great care must be taken to prevent the water or steam getting into the tobacco. It is necessary rather to steam it in its own vapor, and these vapors ought to be kept in while the steam is kept out. Various devices have been tried to accomplish these results. Mr. Brownstein's apparatus is constructed in such a manner that he claims that he can do this.

FIRE ESCAPE.—Elam Dye, S. F. No. 294,860. Dated March 11, 1884. This fire escape consists in a peculiar extensible frame, in the means for operating it, and in certain details of construction. The object is to provide a means for the escape of persons from the windows of a burning building, and for such similar purposes. Sections slide within each other, and there is a cage suspended within the frame sections and adapted to be raised and lowered by a rope and suitable gearing.

VEHICLE.—Jacob Price, San Leandro. No. 297,714. Dated April 29, 1884. This improvement in vehicles consists of a frame, the side pieces of which are formed of continuous bars of flanged or angle iron, with lugs for the attachment of the seat or other parts, and curved strengthening ribs at the points where bends are made. This frame is designed specially for phaeton village carts and light-riding carriages. The side bars are shaped to form the body.

GRAIN SEPARATOR.—Pontalia L. Nash, Hollister. No. 295,668. Dated March 25, 1884. The improvements covered by this patent mainly consist of certain details of construction difficult of intelligent description without the aid of engravings.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First Street, a *Ruthford Pulverizer*, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replenished and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Mining Share Market.

There is not much new to report in mining stock circles. The financial panic in the East did not affect our stock market to any extent. At Gold Hill the Kentucky, Yellow Jacket, Crown Point, Belcher and some other mines are taking out the usual amount of low grade ore. Work has not yet been resumed on the 2800 level of the Hale & Norcross, where the fine prospects were recently found. When work is again commenced there the brokers expect a livelier market. In the Best and Belcher, very favorable indications are found both on the 1200 level and on the 2700 level. The winze below the 300 level of the Mexican has passed through a streak of white, barren quartz, and is now in the dark, compact kind of rock which, in this part of the Comstock, has been found on the east side of the ore veins. The bottom of the winze is perfectly dry, but water will be seen when the ore vein is about to be cut. At the north end the northeast drift on the 300 level of the Sierra Nevada is passing into a new and peculiar formation. The rock somewhat resembles birdseye porphyry, but contains much quartz.

Bullion Shipments.

Don't Fail to Write.

Should this paper be received by any subscriber who does not want it, or beyond the time they intend to pay for it, let them not fail to write us direct to stop it. A postal card (costing one cent only) will suffice. We will not knowingly send the paper to anyone who does not wish it, but if it is continued, through the failure of the subscriber to notify us to discontinue it, or some irresponsible party requested to stop it, we shall positively demand payment for the time it is sent.

Lost Papers.

If any subscriber fails to receive this paper promptly, after making due inquiries at the Postoffice, he is urgently requested to notify this office by letter, that we may send the missing papers, and, if possible, guard against further irregularities.

Scientific, Mining and Other Valuable Books.

PUBLISHED OR ISSUED, WHOLESALE AND RETAIL, BY DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arseniures, and Gold and Silver Ores generally, with 209 Lithographic Diagrams. 1867.

This work is unequalled by any other published embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. Price, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ore without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this industry and in Europe, and the why and wherefore. It contains 150 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. Price, \$3, coin, postage free.

An Easy Binder.

A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price, (size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co.'s journals, Harper's Weekly, and Scientific American), 85 cents; postage to cents. Postpaid to subscribers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Miners' Monthly Circular

WILL BE LET

On Saturday, May 31st,

New Almaden Mines, near San Jose, Cal.</

New Book on Assaying Gold & Silver Ores.

By C. H. AARON.

For Practical Workers—\$1.

This new work is written by an experienced metallurgist who has devoted many years to assaying and working precious ores on the Pacific side of the American Continent. He writes whereof he knows from personal practice, and in such plain and comprehensive terms that neither the scientist or the practical miner can mistake his meaning.

The work, like Mr. Aaron's former publications ("Testing and Working Gold and Silver Ores," "Leaching Gold and Silver Ores") that have been "successfully popular," is written in a condensed form, which renders his information more readily available than that of more wordy and less conscientious writers. The want of such a work has long been felt. It will be very desirable in the hands of many.

Table of Contents:

Preface; Introduction; Implements; Assay Balance Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Latharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scourification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables.

The volume embraces 106 12mo. pages, with illustrations, well bound in cloth; 1884. Price, \$1, postpaid. Sold by DEWEY & CO., Publishers, No. 252 Market street, San Francisco.

N. B. This is Part I of three volumes on assaying by the same author. To be followed by Part II. Gold and Silver; Part III. Lead, Copper, Tin, Mercury. A majority of the best mining publications yet printed have been issued by and are for sale by DEWEY & CO., publishers of the MINING AND SCIENTIFIC PRESS, S. F.

SAN FRANCISCO.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or lift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veinlets of quartz specked with ore. This mine is 11 miles northeasterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize excelled by none—yes, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

GOLD-BEARING BLACK SANDS.

Parties having deposits of Black Sands, as connected with their Hydraulic, Drift or River Mining, may be benefited by corresponding with me on the subject. State quantity to be had, location, class of mining, etc.

Address ALMARIN B. PAUL,

Gold Medals for Best Truss in Existence.

The I-X-L ELASTIC TRUSS has

Corrected more cases in the short period of its existence than all others combined during the last century. Has the Universal Joint movement in the Pad (ball and socket adjustable), making it the most positive, reliable, combining comfort and ease, ever invented, and performs miraculous cures where all others fail. Indorsed by the Medical Faculty of the world. This Truss is not a magnetic or electrical humbug, but an intelligent RAYMOND CURE TRUSS. I-X-L ELASTIC TRUSS CO., Main Office, No. 646 Market Street, San Francisco, Cal.

Iron and Machine Works.

MACBETH'S —PATENT— STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys. They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),

TESTIMONIALS.

ST. LOUIS, MO., Sept. 25, 1883

Messrs. Adolphus Meier & Co., GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER BREWING ASSN.

OFFICE OF SHERIFF OF ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 24, we respectfully inform you that the three boilers in use under your patents, under steam since September 25, 1881, at the Alexander Platz Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

(Signed): BRAUCKE.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE ever invented for the service of Prospectors and others requiring the use of a Horse Power; possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower without interfering with a hoisting apparatus.

It is made entirely of Iron; no piece weighs over 250 pounds. At the ordinary speed of a horse a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope. The cost of erection is slight, as two men in half a day can easily put it in place ready for work.

While this power is more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. SEND FOR CIRCULAR. Address

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the
world. Unlike all other Packings the Jenkins Standard
Packing can be made any thickness desired in a joint by
placing two or as many thicknesses together as desired, and
following up joint, it vulcanizes in place and becomes a
metal of itself (it is frequently called Jenkins Metal), and
will last for years, as it does not rot or burn out. Avoid all
imitations, as a good article is always subject to cheap imi-
tations. The genuine has stamped on every sheet "Jen-
kins Standard Packing," and is for sale by the Trade
generally.

LARD OIL, WEST VIRGINIA LUBRICATING OIL, DOWNER'S MINERAL SPERM SKID OIL, ETC.

These Lubricants have been for the last eight years, and are now, in general use in nearly all the mills, mines and steamers on this Coast, and the fact that the demand constantly increases is sufficient evidence of their superiority.

\$1,000 CHALLENGE!

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinekey, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

VOLUME XLVIII
Number 22.

Mine Models.

Clarence L. Anderson of this city has just patented through the MINING AND SCIENTIFIC PRESS a novel topographical representation or model which will show the surface or subterranean features of a mine and its surroundings. By it one may represent clearly the shafts, drifts, tunnels etc., and also the surface of the country immediately around the mine. The ordinary workings of a mine may, by this device, be readily explained to those interested so as to be easily comprehended, whether in the ordinary course of business or in litigation for the subservience of justice.

The surface contours and interior workings of all kinds are usually shown by maps which give horizontal distances only; but by means of this invention the vertical as well as the horizontal distances are given, which at a glance will give the court, jury or mine superintendent a correct idea of the relative positions of the surface of the ground, the shafts, stopes and other excavations of a mine.

A horizontal datum or base plane is made of wood or other light material, and from the several corners small posts of the desired length are placed to support side-pieces, the upper edges of which represent the surface of the ground on that vertical plane. These side-pieces support the top of the model, which consists of a strip carved to a reduced fac-simile of that portion of the surface-ground which it represents, its edges being a reduced line of contour of the ground at that elevation. To this top piece several ribs are fastened which extend to the side pieces to which they are secured by dowels or screws. These ribs are also curved to represent the slope of the ground radiating from the top, and are necessary to support the other strips which represent more minutely the contour of the surface, their outer edges being carved to reduced lines of the contour of the surface of the ground at the elevations they are placed to represent. The contour-strips are held in place by the ribs and side pieces. The tunnels or drifts are represented by means of pieces of wood carved to a reduced fac-simile of the excavations they represent. These strips or pieces of wood are preferably formed by gluing several thicknesses of veneer together, with the grain of one piece of veneer crossing at or near right-angles the grain of the piece next to it, whereby the pieces are strengthened and stiffened without sacrificing lightness. The tunnels or drifts and the shafts may be vertical or inclined. The pieces representing tunnels or drifts are attached to the strips representing shafts at distances from each other corresponding to the difference in the levels of the tunnels or excavations they represent, and they are held in the proper position in the model by pieces of wire secured to them, and to contour strips, ribs or datum planes.

The stopes are represented by thin pieces of veneer, metal or other material placed in a horizontal position, their edges being curved to a reduced fac-simile of a contour line of the excavation they represent. These horizontal pieces

are fastened together by being screwed, nailed or glued to thin pieces of wood, the edges of which represent a reduced vertical cross-section of a portion of the excavation or stope. When fastened together they are held in their proper places in the model by wires extending from them to ribs, contour strips or the datum plane, as may be required.

THE trial of the suit of Whittier, Feller & Co. against the Castle Dome Mining and Smelting Co. was begun Monday before Judge Greene and a jury, in Department Two of the Superior Court, Alameda Co. The complaint in this case alleges that the plaintiff loaned defendant corporation \$316,032, of which sum and interest \$316,130 have been repaid. The suit is brought to recover the difference, \$50,901.53. The answer avers that the only sum due is \$25,855.34, and also, under special agreement the money is not payable until June 1, 1884; hence the demand is premature. The

Mortars.

The mortars in quartz mills are now usually placed directly upon the vertical mortar-blocks, without any horizontal piece intervening, and are secured in their place by bolts. They have been made with a solid bed plate with sides and ends of wood; but they are now generally made entirely of iron. The mortar for general use in wet crushing on this coast is an iron box four or five feet in length and depth, and twelve inches inside, the bottom sides and ends all in cast in one piece. The feed opening is made three or four inches wide and nearly as long as the mortar. On the opposite side is the discharge opening, furnished with the screen. The opening is as long as the mortar, or nearly so, and 12 to 18 inches deep, the lower edge being two or three inches above the top of the die. In some mortars, especially for dry crushing, the discharge is on both

surface, is apt to wear out faster than the other. A piece of canvass is usually hung before the screen for the crushed ore to splash against as it issues from the mortar.

California-Made Tools.

Among those local industries which have grown rapidly since their commencement, machine tool making is conspicuous. Starting in a small way, in a small shop, the San Francisco Tool Company, under the guidance of a skilled and educated mechanic, has grown in a few years until it occupies now a large four-story building and has as many orders as it can fill. For one firm alone this company now has about \$20,000 worth of work on hand. The tools are made mainly from original designs, and are especially adapted for the work we have to do on this coast. An engraving on this page shows one of the patented improved 17-inch engine lathes made by this tool company. These lathes are made to change instantly from screw cutting to feeding nearly on the same principle as the Bement & Sons' lathes. An important feature is that the apron gearing is so arranged that screws of any pitch can be cut without the use of an extra belt for driving the belt backward, only one driving belt being used. In this way the lathe need not be stopped until the screw is finished. These lathes are made boring bars, dispensing with the ordinary forged tools used for that purpose. They are made with flat-topped frames, and with angular guides for the carriage, as may be desired. The spindles and screws are of steel; bearings of bronze. There are no soft metal nuts, and the whole tool is strong, durable and complete. Another new tool being made by this company is the high-speed drilling machine, a representation of which is given on this page. These machines have no gearing, and are specially suited for small drills to 1 inch diameter. The table is balanced and can be instantly set up or down, or removed from the column entirely, to permit large pieces to be brought under the spindle. The machine requires no counter-shaft, being arranged with the necessary driving pulleys mounted on the main column. The spindles are of steel, and the whole carefully fitted. Drills to the center of pieces 30 inches in diameter. This tool is made to take the place of the larger and more expensive drilling machines. They have no tooth

gearing and are noiseless at any speed, the spindle being driven by belts alone.

COL. A. F. WILLIAMS, whose death was announced last week, surveyed and constructed a number of mining ditches in this State. He was engaged on some of the largest ditches in Nevada county. He brought the water into Oroville, Butte county, and also built ditches at La Porte, Howland Flat and Pine Grove.

OWING to the failure of Congress to appropriate money for continuing the hydrographic branch of the Signal Service, the office in this city will be discontinued after June 30th.

HIGH SPEED DRILLING MACHINE.

RICHARDS' IMPROVED 17-INCH LATHE.

Castle Dome Company was engaged in the production of refined white lead.

HOW A MINE WAS NAMED.—A quartz claim near the town of Graniteville, in the upper part of Nevada county, is called the Hot Water mine. The *Transcript* says it derived its name from the fact that the two bachelors owning it having read that pure hot water was the most healthful and palatable drink ever discovered, some time ago eschewed tea, coffee and stronger drinks, and now confine themselves to hot water, with the very best results to their constitution as well as their purse.

sides, in which case the feed opening is above the screen; but the single discharge is more common. The screen-frame fits in grooves in the mortar and is secured by wedges.

Sometimes screens are vertically placed, but generally there is a slight incline, the latter being thought to facilitate discharge. Several varieties of screen are used. When made of brass wire cloth they have from 40 to 60 meshes to the lineal inch. More generally for wet crushing they are of Russia sheet iron, having finely punched holes varying from one fortieth to one twenty-fourth of an inch in diameter. The wire cloth, while it affords more discharge

CORRESPONDENCE.

We cannot, unendorsed, opinions of correspondents.—Eds.

Gold Saving.

EDITORS PRESS:—Permit me to write a few lines in answer to "Mr. Duval, M. E., of Angels, Calaveras county." He has evidently mistaken the tenor of my letter on "Gold Saving." I thought every one reading that article would naturally see that I was speaking of the treatment of "free gold" only—not of gold chemically or mechanically combined with sulphurets. Judging from the number of letters I have received from all parts of the State and elsewhere on the subject, he is alone in his ideas. My tests and assays have been always made after the sulphurets have been eliminated, then the amount of free gold ascertained. Mr. Duval's letter seems to have but two objects—cynicism on the one hand, and a defense of amalgamators on the other—rather than to look at the matter involved, and offer some remedy; for to deny the existence of the loss is futile and puerile, the opinion of such practical amalgamators as Mr. D. mentions notwithstanding. We want some practical suggestions, that may aid in preventing the loss of the free gold where it exists in such fine particles in the gangue of so many of our quartz lodes in California. Further, I did not base my opinion on the dictum of "incompetent amalgamators, or by the experiments of Tyros who, with no practical experience, attempts to revolutionize gold saving." Such remarks are foreign to the point at issue—said for effect only. The best amalgamators, of long-standing experience, seldom like to admit that they lose any gold by passing off in the slimes, for they have the foolish idea that to admit such would be to confess their own incompetency. Such is not so. It is the appliances and system that is at fault, and not themselves. Further, amalgamators have only a crude idea of the actual value of ore they crush, by the amount of quicksilver the pulp takes, which of course is shown by the condition of the outside plates. This tell-tale plate is very uncertain under different and various conditions—muddy water, much base metals in gangue, temperature of water, and numerous other obstacles that present themselves to the millman. Certainly, the object of my article was to obtain the opinion of all practical millmen and mining men towards arriving at some solution of the problem of free gold "saving," to obtain the maximum amount by some better process than the stamp mortar amalgamation, and by trying to save gold by running water down stream. Willard M. Duval, another question. What use are statistics when compiled by scientific men, if we are not to make use of them? or are we to take all such productions *cum grano salis*? I am pleased that my letter interested Mr. D., and would like him to aid the matter by some practical suggestion that may lead to an absolute revolution of the present old and faulty system. He will be a public benefactor, and our letters will have done some good. WM. F. DRAKE, Superintendent Patterson Mine.

Progress in Mine Engineering.

In the economical underwatering of mines no very manifest progress has been made in modern times. Forty or fifty years ago the Cornish pumping engine had been brought to a degree of efficiency and economy which has not been surpassed by any more recent type, but its large first cost and generally ponderous character has led to the introduction of many forms of direct acting engines, cheaper, simpler and more easy of application, if somewhat less economical in subsequent working. Many of these placed underground are now forcing columns of water to vertical heights of as much as 600, and up to 1,100 feet, the only incumbrance in the shafts being the steam and water pipes, and as the pumps are double acting and the flow of water practically constant, these pipes for a given discharge may be very considerably smaller than would be required for ordinary lift-work. Direct acting engines are either rotary (controlled by a fly-wheel) or non-rotary, and of the latter class the one designed by Mr. Davey, with his beautiful differential valve gear, may be cited as an excellent example. This valve gear has also been applied to control Cornish engines, with the best results. As might be expected under such heavy water columns, some trouble has been experienced with the valves or clacks, and Mr. Davey has got the best results from a modified form of Harvey and West double beat valve. Direct acting pumps actuated by hydraulic power have been found very useful in draining dip workings, the dispensing with rods and substitution therefore of a simple line of pipes being a very great convenience, and at Clanshal a pair of rotary engines has been erected, driven by a hydraulic head of 1,950 feet, the pumps being 13 inches diameter and 24½ inches stroke, capable of forcing at 12 revolutions per minute 330 gallons to a height of 750 feet, the percentage of useful effect being 35. At lower speeds this duty sinks, and at three revolutions is only 15 per cent, and the cost of the installation was very great. It could only be under very exceptional circum-

stances that this would be repeated. In Germany, Rittinger's pump, with a tubular rod, is regarded very favorably, and has of late been extensively adopted. Amongst minor, but important details, the substitution of wrought iron for cast in main engine beams may be mentioned, the form given being either rolled slabs, as at Clay Cross, or built up plate web girders.

In metalliferous mines, and especially in Cornwall, where fuel is costly, great attention has always been paid to the construction and setting of boilers, and to contrivances to economize fuel. It is only in recent years, however, that the increasing value of small coal, and perhaps less indifference among managers, have caused these matters to receive the attention at collieries to which they are entitled. And accordingly we find the antiquated egg-ended, externally fired boiler has followed in the wake of its predecessors—the "hay-stack" and "waggon," and has been displaced by the Cornish or Lancashire flued boilers, often with conical tubes and sometimes with mechanical stokers, and where coking is practiced the escaping gases, instead of being a nuisance in the vicinity, are now conducted under the boilers and utilized in the generation of steam. In some cases, by the aid of gas producers, refuse coal is thus utilized, which boilers, pipes and cylinders are carefully covered to prevent waste of heat (silicate and cotton being about the best material for the purpose), and the warming of the feed water in some manner by otherwise waste heat is very generally practiced.

That very difficult problem how safely to light our fiery mines remains unsolved. No very great advance has been made in recent years, and we still await the discovery of a safe safety-lamp. The lamps invented by Davy, Stephenson and Clanny, nearly 70, and by Mueseler over 40 years ago, none of which are absolutely safe, are still in very general use. The simple expedient of placing the Davy in a close shield of tin can has diminished the risk, and the Marsant improvements have added to the efficiency of the Mueseler. In some collieries it is now the practice to test each lamp before use by contact with or immersion in gas. The electric light is in use for lighting surface operations, such as screening, etc., for which it is well fitted, and it has been tried underground but not with very satisfactory results. As a miner's lamp none of the forms yet proposed are of service. The miner's lamp must be self-contained, no lamp requiring a detached battery or having wires attached is of any use; it must give at least 12 hours sustained light, must be portable and admit of being placed in almost any position to suit the requirements of the moment, and ought not to exceed three to four pounds weight in its complete state, and it must not require any but the very slightest attention on the part of the miner to keep it in order during work.

The furnace as a means of producing a current of ventilation is being rapidly superseded by mechanical means. More than three centuries ago fans were in use on a small scale for this purpose, but it is only in recent years that they have been employed of sizes and capabilities commensurate with the magnitude of modern collieries. The several types in common use, with their efficiency, may be classed as follows:

Type.	Name.	Efficiency, per cent.
Closed case fan.....	Griffith.....	40 to 61
Closed case fan.....	Schuler.....	46 to 49
Open running fan.....	Waddle.....	53
Displacement machines.....	Struve.....	58
Displacement machines.....	Root.....	48
Displacement machines.....	Nixon.....	46
Displacement machines.....	Gooke.....	37
Displacement machines.....	Leniellie.....	24
Screw.....	Pelzer.....	3

The best fans are decidedly more economical than furnaces, and even were not this so, their greater safety ought to lead to their exclusive adoption in every mine in which there is a possibility of explosive gas being met with.

Although in the means of generating a powerful ventilating current we may claim considerable improvement, the best methods of distribution are not always practiced, and notwithstanding that nearly 80 years have passed away since Buddie introduced the system of splitting the air and district or panel airing, we find collieries where the advantages thus to be gained are lost sight of. In steep mines also more attention should be paid to ascensional ventilation.

To ascertain the quantity of air passing through a road it is no longer necessary to guess by the aid of a puff of powder smoke or by carrying a candle with flame kept upright as did our fathers. We possess now very accurate and reliable anemometers which 50 years ago were quite unknown, those of Biram (revolving vanes) and Dickinson (vertical vane) being most convenient and largely used.

In what state does fire-damp exist in situ, and what are the effects of varying atmospheric pressure upon its liberation? and is the barometer of any value as a warning of coming danger? These are questions which early attracted attention, and have been much discussed. Mr. Wood has carried out a most extensive series of elaborate and careful experiments to ascertain the conditions as to the solid coal, and Mr. Corbet has rendered a similar service in respect of goafs, and the conclusion seems to be in both cases that the barometer affords no reliable indications when to expect danger from gas in mines.

The influence of coal dust in explosions has been carefully investigated, and though it is not established that dust alone may be the cause of an explosion it is conceded that in a dusty

atmosphere the addition of a smaller quantity of fire-damp is requisite to bring it to the explosive point, and that the effects of an explosion may be intensified and extended by the presence of dust, and accordingly in many very dry and fiery mines the main roads are kept regularly watered, or still better, by sprinkling salt upon the dust the same object is attained without the liability of causing the floor to heave and swell. Several instruments have been devised for detecting the presence of minute quantities of fire-damp in air, such as those of Forbes, Ansell and Liveing, but none of them are of any practical use to the operative miner, and they are chiefly interesting as very ingenious scientific toys.

A review of progress would not be complete without some mention of the increased safety with which coal mines are now worked. In 1851 the deaths from accidents of every kind in the coal mines of the United Kingdom were 4.56 per 1,000 people employed, while in the decade ending 1860, the ratio was 4.07, in the decade ending 1870, it was 3.32, and in the decade ending 1880, it was 2.35, and for the two years 1881-82 the ratio is 2.081. Without attempting to go minutely into particulars it may be briefly stated that this marked improvement is entirely in those classes of accidents in the prevention of which improved machinery and appliances, increased knowledge, better discipline, and more competent supervision may be expected to have greatest effect. While on the subject of accidents mention may be made of the Flenns apparatus, by aid of which the explorers at Seaham Colliery were enabled to penetrate into the workings a distance of 400 yards in an irrespirable atmosphere. In cases of accident causing serious injury, the patient's sufferings have often been intensified by his being jolted to his home in a stiff springless cart, but the labors of the St. John's Ambulance Association have extended a knowledge of how to give first aid, and ambulance or stretchers of a simple kind, by which the pain consequent on removal is much lessened, are now provided at many large mines, and ought to be at all.—London Mining Journal.

Mines and Mining in Arizona.

These be stale subjects upon which to write, says the Prescott Courier, and yet an article upon them is always in order, or should be, in a country like Arizona, where mining is certainly a leading industry. Less than 30 years ago venturesome men took their lives in their hands, as the saying is, and started the quartz mining industry in southern Arizona. They merely succeeded in proving the mines valuable, when the Apaches forced them to abandon work. The war of the sections soon followed, and almost put a stop to industry of every kind in Arizona. Its close did not help matters much, for the Indians still remained and would not permit development. It was not until in 1873, after General Crook and his soldiers had subdued the savages, that the work of exploration was really begun in the territory. The splendid mines of Tombstone were soon after discovered and worked. The Silver King and scores of other mines were made good use of, and immediately raised the reputation of the territory. We have now ten counties, all of which, save one, are well filled with metals and minerals. Nevada had but two great mining camps, Virginia and Eureka. Arizona has already Tombstone, Silver King, Vulture, United Verde, Quijotoa, Mineral Park, Signal, Clifton, and many others we might name. Although old, these camps are still very lively places. Until recently the southern counties have led in mining; now the counties of the north are coming forward, and will, without doubt, shortly take the lead.

Two transcontinental railroads have aided the people of this territory to unearth vast treasures, but the country now demands, north and south, railroads with branches to the richest mining districts. These we are promised at an early date. They cannot be given us too soon; our people are ready for them. They will traverse sections of country which are rich in gold, silver, copper, lead and other metals, as well as in timber, farming and grazing lands. They will open up Tonto Basin, the Mogollon forests; they will connect Mineral Park, Flagstaff, Ash Fork, Williams, Prescott, Phoenix, Tempe, Florence, Casa Grande, Tucson, Tombstone, Benson, Yuma, Globe and other leading towns; will make the people of the sections more homogeneous, and will bring in more people to help us develop our great resources.

As every section of Arizona has at present newspapers to "spread the news," the Courier will, we hope, be pardoned for "coming home" and saying that with such mines as are in United Verde, Copper Basin, Big Bag, Peck, Walker, Turkey Creek, Weaver, Walnut Grove, Bradshaw and other districts, Yavapai county, of which Prescott is the capital, will, ere long, be shipping more gold, silver, copper and lead than any other county of the territory. When the railroad shall have been built, miners who at present take tools, food, everything, over rough mountain trails on the backs of animals, or in wagons, will be enabled to work low-grade mines. Just now it is only the richest mines that will pay to work, and with transportation, food, everything going slow at enormous prices, the wonder is that our miners can even "make ends meet."

The Mining Situation in Nevada County.

If Nevada county was off from almost any other place and was buried under twenty feet of snow for ten months of the year, during most of which while the thermometer stayed at forty degrees below zero; if during the summer season there were no trees in Nevada county to cast a shade, Nevada county would have now what is called a mining boom. Districts of country that are scarcely accessible and that have no comforts or conveniences have those booms, while at the same time they have not the fortieth part of a good showing of precious metals that Nevada county now has. But Nevada can be easily reached from any part of the world, has good roads over which travel is delightful, has trees and flowers and fruits and has a climate to which no reasonable person can object and therefore she has no mining boom, although she has gold in thousands of ledges and in many beds of gravel. Distance, difficulty and discomfort, give enchantment to a mining district and attract prospectors as well as capital.

While there is mining merit in Nevada county the miners here must show it up, and tell the world about it. Neither labor nor capital will come from a distance to hunt mines for our people. They will go to a new place on the bare report of a gold discovery, but not to an old place. When they are told that better mines are here they will naturally and sensibly say: "You folks have been there for a long time, and why do you not develop the mines you say can be developed?" Those distant people will acknowledge that we have an Idaho, Empire, Providence, Wyoming, Peabody, Magenta, New York Hill and other mines of which our history has often spoken, but when told that there are several hundred ledges held here, and by good titles, and are not worked, but which will pay when worked, those distant people and outside money will not believe. The only way is to work our ledges ourselves as best we can, show that they have in them the makings of mines and then capital will take hold.

We are glad to say this course is being more generally followed at the present time than has been heretofore the case. Eureka township has many quartz ledges in the vicinity of Graniteville (Eureka South) and some of them have paid well, notwithstanding which fact work ceased when the pitiful depth of one or two hundred feet was reached. The money taken from the mines was divided among owners and not carried over for the "rainy day" when heavier machinery was necessary. In Bloomfield township miners are looking at quartz, something they would not do a few years ago. Then they had too much gravel rich in gold to think of quartz mining. Now they have some promising locations on ledges, and are making some showing for having mines that will last, and to which a valley farmer cannot object. In Rough and Ready township, much good work is being done. Ledges that bear mineral are very numerous in that township, and they have only been worked far enough to have their croppings knocked off by a hammer. Washington township is known to have many large and innumerable small ledges. Wherever work has been done in Washington township good pay has resulted. The country rock there is similar to that of the paying part of Nevada City and Grass Valley districts. We think Washington township presents the best field for intelligent mining prospecting of any district on the coast. In Nevada City and Grass Valley districts (an imaginary line divides the two), much work by owners of undeveloped ledges is going forward in the proper way. The established mines are pushing ahead with explorations, and are using all the improvements of machinery and power which make mining more profitable, and which at the same time give employment to labor.

On the whole, we are very hopeful that a bright future is before this county, and that hope is founded on the good reasoning of practical men, who keep always alive to the situation. Moreover, that good future is close at hand.—Tidings.

Arizona Industrial Fair.

That the industries of Arizona are advancing may be inferred from the fact that there has just been incorporated an association for holding a Territorial fair at Phoenix. The name of the organization is to be "Arizona Industrial Exhibition Association," and the object is declared to be to "hold annual fairs or exhibitions for the display of all classes of domestic animals and fowls, and the various industrial products of all parts of the Territory. And to this end to lease or purchase a suitable tract of land for fair grounds; to erect all necessary halls, buildings, corrals, pens and stalls for the proper display of all classes of domestic animals and fowls, and all agricultural, horticultural and mineral products; all articles of husbandry and housewifery, and all manufactured articles, wares and merchandise."

Perhaps this announcement may arouse many who think of Arizona only as a torrid waste to revise their opinions. The Territory is advancing rapidly, and is building up a respectable agricultural interest in some parts. We trust the proposition for a fair will go forward rapidly and result in success worthy of such enterprise.

MECHANICAL PROGRESS.

Do Belts Need Rest?

A correspondent of the Boston *Journal of Commerce* says: Belts need rest just as much as a work hand, and room should be made to run off every belt at night with hoops to hold them where they will not become injured, unless it is a belt working on a loose pulley that is made smaller than the one with which it works. My reasons for so doing are that belts are elastic and continually stretching from the time they are first put in use, and if kept constantly under a strain their length will keep on increasing till they will at last break. Leather, from which the best belts are made will sustain a heavy load for a few moments, but will not pull back the strain if left under a continuous pull month after month. Its elasticity is such that it requires time for the belt to resume its former thickness when stretched till the parts separate. Each individual fiber, in assuming its new position as the belt is lengthened, suffers in thickness and not in a relation with one another, and, if time is allowed, the belt will shorten and thicken as the elasticity of each fiber has restored its effect of elongation.

It has been noticed in my experience, many a time, where a belt that would fail to drive a shaft at night would be ready to take hold in the morning, and perhaps would drive without any trouble for the greater part of the day. I know of belts that have never taken a rest in stretching from the time they were first put in use, that need to have about one-half inch removed every month to keep them from working slack, while others will work three times as long without removing any of the belt that has had a chance to restore the effect of stretching while removed from their wheels. The life of a belt, for this reason, depends on the time it takes for a given load to stretch it out to its breaking point, and since it has the power to restore itself in the amount of stretch, or to draw itself back into the shape and thickness it had to start with, it is simple enough to understand that every moment a belt has a chance to rest this drawing back adds to the life of the belt by giving it a chance to stretch over the same road again, and as long as we are able to give the belt a chance to restore at night what it has lost during the day, it is plain to be seen that they must wear out in some other way than by continually giving out by stretching.

I am well aware that a new belt stretches the most the first day it is in use, but this rapid stretching is soon over with. Belts will stretch in a short time all that they are going to until the fibres get settled down to their work, but from this point they will suffer elongation which their elastic powers are going to restore; and sometimes I have seen belts wound tightly on a drum or wheel that they may be ready to work when laced up for use. There is a load that a strap of leather will sustain which will never reach the breaking point the elastic power of the fibres are able to sustain, or the strain brought upon them; but when the belt is in motion these strains are changed about, sometimes acting on those of the inside layer, and then on the central ones, while being drawn over the smallest pulley, causing the interlaced fibres to work down between one another, and giving the belt a chance to stretch, which may partly itself while the belt remains on the pulleys. But in this case there is as much lost in one side or the other suffering compression, and from the driving stretch of the belt remaining under a severe tension when the machinery comes to rest.

If I had belts on every length of shafting, I would fix up some easy way of removing them at night, and of replacing them when the work is to be started in the morning, without injuring the leather by cutting over the sharp edges of the pulley, or by hanging on slender hooks, or stringing up by small cords to keep them from the shaft, and give them a chance to rest when they can do so as well as not, even if a belt was only to be used while the machine was in actual operation, and thereby save much power, for how often a belt is found that has been entirely worn out by grinding a loose pulley to death.

Properties of Brass.

The most important properties of brass compared with copper are the following: The color of brass is much brighter and more approaching to that of gold; it is more fusible than copper, less subject to rust, and to be acted upon by the vast variety of substances which corrode copper when cold, and more extensible than either copper or iron, and hence is well fitted for fine wire. Brass, however, is only malleable when cold. Hammering is found to give a magnetic quality to brass, and this circumstance makes it necessary to employ unhammered brass for compass boxes and similar apparatus.

The expansion of brass has been very accurately determined, as this metal is most commonly used for mathematical and astronomical instruments, where the utmost precision is required.

Most of the zinc readily burns off from brass when kept melted in a strong heat with free access of air. When the heat is equal to that of melted copper, the zinc takes fire and slowly burns away. At last, little else but copper remains, but still united with a small portion of zinc, which no further continuance of the fire will entirely separate.

Some kinds of very fine brass are said not to

be made by cementation, but by a more speedy and direct union of copper and zinc, care being taken to prevent the access of air to the materials while in fusion. Very fine brass may also be made by mixing together the oxides of copper and zinc and reducing them with a carbonaceous flux. Sage gives the following experiment to this purpose: Mix together 50 grains of the oxide of copper, remaining after the distillation of verdigris (which is very pure), with 100 grains of lapis calaminaris, 400 grains of black flux, and 30 grains of charcoal powder; melt the mixture in a crucible till the blue flame is seen no longer round the lid of the crucible, and when cold a fine button of brass is found beneath the scoria, weighing a sixth more than the copper alone, obtainable from its oxide in the same way, but without the calamine. This brass has a very fine color, like gold.

On this experiment M. Sage observes that there appears to be a point of mutual saturation between the two metals, which is when the copper retains one sixth of zinc, and this portion it will retain however long it is heated, provided the surface of the melted metal be covered to protect the zinc from the action of the air; but if the brass contains a greater proportion of zinc, precisely this excess will escape, even in covered vessels, and will burn when it comes out to the air. — *Reporter.*

A Metallurgical Triumph.

A very clever writer, Andrew Carnegie, gives the following racy description of how Messrs. Thomas and Gilchrist succeeded in devising their now famous process for eliminating phosphorus from iron. The story reads almost like a fairy tale. This writer says: "In making steel ten tons of molten pig iron are run into a big pot called a converter, and hundreds of jets of it are blown up through the mass to burn out the silica and carbon, and finally to make it steel. Now, phosphorus has a greater affinity for lime than for iron when it reaches a certain temperature, and when the air-blast brings the mass to the required heat, the million particles of phosphorus, like so many tiny ants disturbed, run hither and thither quite ready to leave the iron for the lime. In experimenting to get rid of the phosphorus, these clever young men (Thomas and Gilchrist) first put a lot of lime in the bottom of the pot as a bait, and into this fly the ants, perfectly delighted with their new home. The lime and slag float to the top, and are drawn off; but, mark you, let the temperature fall, and the new home gets too cold to suit these salamanders, although the temperature may be over 2,000 degrees—hot enough to melt a bar of steel in a moment if thrown into the pot. No; they must have 2,500 degrees in the lime, or they will rush back to the metal.

"But here lay a difficulty: 2,500 degrees is so very hot that no ordinary pot lining will stand it, and, of course, the pot itself will not stand a moment. If ganister or fire-brick is used, it just crumbles away, and besides this, the plaguey particles of phosphorus will rush into it and tear it all to pieces. The great point is to get a basic lining—that is, one free from silica. This has at last been accomplished, and now the basic process is destined to revolutionize the manufacture of steel; for out of the poorest ores, and even out of puddle cinder, steel or iron much finer than any now made for rails or bridges can be obtained, and the two young chemists, patentees of the Thomas-Gilchrist process, take their rank in the domain of metallurgy with Cort, Nelson, Bessemer and Siemens. These young men have done more for England's greatness than all her kings and queens and aristocracy put together."

It is claimed by many builders that wood joists, encased in plaster, are proof against any ordinary fire, and for many reasons are much preferred by them to the ordinary regulation fireproof iron joists. Strips are attached to the joists, over these strips irons are run, and on these the plaster is spread. The theory is that in any ordinary fire these joists thus treated will be fireproof, and only when the fire has reached such a fury that the building must go anyway will they be affected. Here comes in one of the advantages claimed for them. When a building is being burned by a furious fire the iron joists expand and crush out the walls, and do other damage. The wood joists would simply be burned up without injuring the walls at all.

CASTING A HEAVY GUN.—On May 6th, the largest gun ever constructed in this country was cast at the South Boston Iron Works, in fulfillment of a contract with the Government. When completed the gun will be about thirty feet in length, of twelve-inch rifle, weighing 212,000 pounds, and worth \$28,000, about half the sum that a steel gun would have cost. It is calculated to be able to throw a projectile six miles. This company is also under contract to furnish to the United States a ten-inch wire-wrapped cast iron rifle gun, a twelve-inch rifled mortar, and another gun similar to the one cast, but shorter.

FIRE-PROOF CEMENT.—(1) Iron filings, 140 parts; hydraulic lime, 20; quartz sand, 25; sal ammoniac, 3. These are formed into a paste with vinegar and then applied. This cement is left to dry slowly before heating. (2) Iron filings, 180 parts; lime, 45; common salt, 5. These are worked into a paste with strong vinegar. The cement must be perfectly dry before heated. By heating it becomes stone hard.

SCIENTIFIC PROGRESS.

A New Theory of Magnetism.

While it is now considered by scientific theorists as established beyond peradventure that the various manifestations of energy that we call light, heat, electricity, etc., are simply so many different modes of motion that affect the ultimate particles of which matter is composed, there is still much doubt and speculation as to the character of these motions, their mode of propagation, transference, etc. Especially is this the case with the peculiar manifestation of energy known as magnetism, which has been the puzzle of many master minds in science. In spite, however, of much ingenious speculation, it may safely be affirmed that no theory has yet been advanced sufficiently satisfactory to account for all the facts.

These remarks are apropos to a lecture lately delivered by Prof. D. E. Hughes, of microphone fame, before the London Society of Telegraph Engineers and Electricians, on the "Cause of Evident Magnetism in Iron, Steel, etc.," and which will take rank in the future, we believe, as one of the most important contributions to physical science that has been made in our day. They are summarized by a contemporary as follows:

Mr. Hughes was led to the long series of investigations, which finally culminated in the formulation of a new theory of magnetism, by some unexpected observations which were inexplicable by any of the current theories, and proceeded step by step experimentally verifying his position as his investigations proceeded, until he has finally succeeded, beyond question, in proving the complete inadequacy of any of the theories already promulgated to account for his observed facts; and, furthermore, he has advanced a new theory to account for the cause of evident magnetism, which is not only in harmony with our knowledge of the subject, but which is likewise substantiated by an imposing array of new and ingenious experiments which present many new and unexpected phenomena which are quite inexplicable by any of the theories now entertained.

The result of Mr. Hughes' investigations are attracting much interest among scientists, and are of decided importance as affecting our conceptions of the conditions under which one of the most interesting forms of energy manifests itself. The conclusions which he announces are as follows:

1. That each molecule of a piece of iron, steel, or other magnetic metal, is a separate and independent magnet, having its two poles and distribution of magnetic polarity exactly the same as its total evident magnetism, when noticed upon a steel bar magnet.
2. That each molecule, or its polarity, can be rotated in either direction upon its axis by torsion, stress or physical forces, such as magnetism and electricity.
3. That the inherent polarity or magnetism of each molecule is a constant quantity like gravity; that it can neither be augmented nor destroyed.
4. That when we have external neutrality, or no apparent magnetism, the molecules, or their polarities, arrange themselves so as to satisfy their mutual attraction by the shortest path, and thus form a complete closed circuit of attraction.
5. That when magnetism becomes evident, the molecules or their polarities have all rotated symmetrically in a given direction, producing a north pole if rotated in that direction, as regards the piece of steel, or a south pole if rotated in the opposite direction. Also, that in evident magnetism we have still a symmetrical arrangement, but one whose circles of attraction are not completed except through an external armature joining both poles.
6. That we have permanent magnetism when the molecular rigidity, as in tempered steel, retains them in a given direction, and transient magnetism whenever the molecules rotate in comparative freedom, as in soft iron.

These experiments do away with the theory of Coulomb and Poisson, that each molecule is a sphere containing two distinct magnetic fluids, and a peculiar coercive force. The theory of Ampere that elementary currents flow around each molecule is shown to be equally illusive.

The inherent polarity of magnetic metals is sought to be proved by numerous experiments. The Professor says: "We might suppose from the theory which I am advocating that upon the rotation of the molecules there would be some disturbance or mechanical trepidation; and such is found to be the case, as first observed by Page, and afterwards verified by Dr. Joule and De la Rive, in the molecular sounds produced in iron upon its magnetization. Reis's first telephone was founded upon the sounds, and Du Moncel has made numerous researches upon this subject. In the last of my experiments, the sounds were too feeble to be heard, but by the application of the microphone these trepidations at once became audible."

One of the most interesting conclusions that Prof. Hughes believes himself justified in announcing from his experiments, is the discovery of a peculiar property possessed by a magnetic body, and which he explains as follows: "That not only can the molecule be rotated through any degree of arc to its maximum or saturation, but that while it requires a comparatively strong force to overcome its rigidity or resistance to rotation, it has a small field of its own, through

which it can move with excessive freedom, trembling, vibrating or rotating through a small degree with infinitely less force than would be required to rotate it permanently on either side. This property is so marked and general that it can be observed without any special iron or apparatus."

It is not improbable that the further development of this highly interesting and original series of experimental researches may lead to the discovery of simple means, whereby the character and quality of iron and steel may be determined without the intervention of the present tedious and troublesome chemical and mechanical tests—indeed, the lecturer held this suggestion to be most probable. Furthermore, it is not improbable that much light may be thrown upon the cause of these inexplicable changes in the molecular structure of iron and steel, which are of such grave importance when considered in relation to the very general uses of these metals for various constructive purposes.

BACTERIA ON SMALL COINS.—The *Frankfurter Zeitung* informs us that Dr. Reusch has found, as the result of a long series of minute investigations, that the surfaces of 50-pfening pieces (sixpences), which have been long in circulation, are the home and feeding ground of a minute kind of bacteria and vegetable fungus. An extended series of observations showed that this is the case with the small coins of all nations, the thin incrustation of organic matter deposited upon their surfaces in the course of long circulation rendering them very suitable for this parasitical settlement. Dr. Reusch scraped off some of these incrustations, and with a small scalpel divided them into fragments, which were subsequently dissolved in distilled water. The employment of lenses of very high power showed the bacteria and fungi distinctly. This is a matter of no little importance from a hygienic point of view. It has now been conclusively established that bacteria form the chief agency in the propagation of epidemic disease. The revelation that they have a chosen domicile in the most widely circulating medium which probably exists in the world, presents us with a new factor in the spread of infectious disease. There is, however, a remedy. Where coins have been in circulation for a number of years, if they are washed in a boiling, weak solution of caustic potash, they will be cleansed from their organic incrustation, and so freed from the unwelcome guests which they harbored.

MANGANESE IN MARBLE.—M. Dieulafoy has shown that manganese in the state of bicarbonate exists in the waters of all seas and oceans; and M. Berthelot has pointed out that in contact with oxygen, this bicarbonate becomes binoxide. It follows that oxides of manganese must be produced in large quantity in the ocean, and sinking by their weight must accumulate on the ocean bed. This corollary explains the existence of the large quantities of binoxide of manganese concretions and mangiferous mud found in the sea bed. It also explains the existence of manganese in the French and English chalks of the secondary period; also the fact recently discovered by M. Dieulafoy that the well known artistic marbles of Carrara, Paros, and the Pyrenees are comparatively rich in manganese. There are two kinds of Carrara marble: the ordinary, which has a bluish tinge on fracture, and the statuary marble, which is very pure and white. The well known chemical reaction showed manganese in both kinds. Parian marble, which has larger grains than Carrara, also showed manganese in even greater proportion than the Carrara; and the Pyrenean marbles, which resembles the Carrara in being of two qualities, also contain manganese in about the same proportion. The agreement in proportion seems to indicate a similarity of cause for the presence of the manganese.

ANALYZING DRINKING WATER.—A contemporary gives the following simple method for analyzing common drinking water: Place the water in a clear bottle, and first examine if it be colorless, and thus free from organic matter. Then taste it, and if no peculiar flavor is discernible, let it stand a day or two; then heat or boil, and if no odor is present, the water is in all probability, pure. If the presence of sewage contamination is suspected, fill a clean pint-bottle three-fourths full of water, dissolve a teaspoonful of loaf or granulated sugar, cork the bottle, and place it in a warm place for two days. If the water becomes cloudy or muddy, it is unfit for domestic use. If it remains perfectly clear, it is probably safe to use. If the water is sufficiently concentrated, it will give a blue precipitate with potassium ferrocyanide when iron is present, and a black precipitate with hydrogen sulphide if lead is present. It would be unwise to attempt these tests without some previous knowledge of chemistry.

SEEING A LIGHTNING FLASH.—Prof. Tait, of Edinburgh, insists that when people think they see a lightning flash go upward or downward they must be mistaken. The duration of a lightning flash is less than the millionth part of a second, and the eye cannot possibly follow movements of such extraordinary rapidity. The origin of the mistake seems, he says, to be a subjective one, viz.: that the central parts of the retina are more sensitive, by practice, than the rest, and, therefore, that the portion of the flash which is seen directly affects the brain sooner than the rest. Hence a spectator looking toward either end of the flash very naturally fancies that end to be its starting point.

TABLE OF CONTENTS.

EDITORIALS.—Mine Models; Mortars; California-Made Tools, 365. Passing Events; Smelting Native Copper Ores; Estimation of Slags; Averages in Mine Accidents; Bismuth; Freezing Water in Mine Shafts; Construction of Bratticings, 368. Lower Wood River; The Assessment Plan; Technical Training, 369.

ILLUSTRATIONS.—High Speed Drilling Machine; Richards' Improved 37-Inch Lathe, 365. Map of Lower Wood River, 369.

CORRESPONDENCE.—Gold Saving, 366.

MECHANICAL PROGRESS.—Do Belts Need Rest; Properties of Brass; A Metallurgical Triumph; Casting a Heavy Gun; Fire-proof Cement, 367.

SCIENTIFIC PROGRESS.—A New Theory of Magnetism; Bacteria on Small Coins; Manganese in Marble; Analyzing Drinking Water; Seeing a Lightning Flash, 367.

ENGINEERING NOTES.—Great Bridges; Sanitary Engineering; Another Big Bridge; A Double Cable Road; Cape Cod Canal, 371.

USEFUL INFORMATION.—Boreh Oil; Street Dangers Increasing; Digging Wells; To Bronze Iron or Steel; What the Zero Mark Means; Cotton Belting; Geysers and Springs in the Yellowstone Park; Deep Drive Wells; Colors in the Electric Light, 371.

GOOD HEALTH.—Elevated Railways Cause Eye Troubles; Oily Skins; An English Cough Remedy; Food and Nutrition; A Remarkable Case of Trance; Sherry and Cider; Birds and Epidemics; Hot Milk as a Restorative; Hot Lemonade for Diarrhoea; Charcoal Poultice, 371.

MISCELLANEOUS.—Progress in Mine Engineering; Mines and Mining in Arizona; The Mining Situation in Nevada County; Arizona Industrial Fair, 366. Bony; Russian Mines; Mining Resources of El Dorado County, 370.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 372-73.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 376.

Passing Events.

It is worthy of note that the late news from the Coeur d'Alene region indicates rather the discovery of ledges than the opening of any larger area of placer ground than was known last fall. It is too soon, of course, to form a very correct judgment of the value of these quartz discoveries, but the claims will be actively developed.

The legal holiday of "Decoration Day" was very generally observed this year. Not only has it become the custom to decorate on this day annually the graves of the soldiers of the war, but families take the occasion to visit the cemeteries and place flowers on the graves of deceased friends and relatives.

So far this spring, although there are many prospectors in the mountains, no discoveries of any special note, which are liable to open up new areas of any extent, have been made.

The announcement that ex-Governor Stanford, of this State, proposes establishing a school on his extensive property at Palo Alto, San Mateo county, where young men may receive an "industrial education," is received with pleasure. His abundant means will permit of his establishing an institution which should be of great value to the industrial classes.

STATE MINERALOGIST.—The Governor has re-appointed Mr. Henry G. Hanks State Mineralogist of California. The funds of the Mining Bureau are quite low, so much so that the Governor has suggested moving the mineral collection to the Capitol building, at Sacramento, to save rent, in which case the mineralogist would simply keep a business office in this city. It is to be hoped this will not be done, however.

Smelting Native Copper Ores.

The product of the Lake Superior copper mines reaches the lake smelting works in one of three forms—masses, barrel-work, or concentrates. The masses, from the veins only, sometimes exceed 10 tons in weight. Barrel-work is the larger lumps, and the concentrates average between 70 and 75 per cent. As the mineral is free from sulphur, arsenic and antimony, it is only necessary to smelt it with from 6 to 8 per cent of limestone and 10 per cent of rich refinery slag, skim off the slag and refine the metal.

The mass copper furnaces have a removable roof, lifted by a crane, to admit the mass. The charges of barrel or stamp work are thrown in with the fluxes by a side door. About 75 per cent of the copper is ladled out in ingots, and 25 per cent passes into the slags. The refinery slags are returned to the furnace with the next charge, the poorer being run down in a cupola.

The cupola charge consists of 20 tons of slag, containing about 4 per cent of copper, 8 to 9 tons of limestone, and 6 to 7 tons of anthracite coal. The yield of the cupola is slags poor enough to be thrown away and cake copper fit for refining. Mr. James Douglas, Jr., describes the cupola used as a modified McKenzie with an annular tuyere five-eighths of an inch wide, encircling the furnace below, and a slightly conical water-breast, 22 inches high and 25 inches above the hearth. Upon the water breast rests the brick body of the furnace, 8 feet 8 inches high to the charging door, elliptical in shape, being 7 feet 9 inches by 5 feet 8 inches. The brick lining immediately above the bosh supplies the iron of the slag with silica, and is so rapidly consumed that a 10 or 12 hours' run is almost the limit of its life. During these short campaigns 20 tons of slag are put through.

The construction of the Lake Superior refineries, if we except the removable roof of those used for the mass copper, does not differ materially from that of the ordinary Swansea furnace, but special valves and deflecting plates are employed to throw the air through vents in the bridge on to the charge. The ash-pits are provided with doors, and a low-pressure blast is used beneath the fire-bars, so as to control the admission of air and the character of the atmosphere within the furnace.

Estimation of Slags.

In the early stage of smelting at Leadville great difficulties were encountered at most of the works in making a good slag, and the "muscular" method had to be frequently resorted to in freeing the furnace from sows. This evil was in great part due to disregarding the alumina contained in the ore, and also to the manganese which was not regularly determined on account of the tedious methods then in use. The result of this oversight was a very basic slag, which would naturally close up the furnaces. Mr. T. Macfarlane, in a paper read before the American Institute of Mining Engineers, suggested that by determining the specific gravity of a slag, a clue might be obtained for improving it if not correct. If the specific gravity were higher than that of the typical slag this would prove an excess of the bases of the heavy metals in the faulty one. But whether it required an addition of silica or lime, or both, the determination of the specific gravity could not tell us. In the case of a slag which is far out of the way, correct chemical analysis alone, however tardy it may be, can give us information. Since the introduction of the more rapid volumetric method for the determination of manganese (for example, Guyard's), and the estimation of the alumina in slag computations, all troubles of this nature have ceased.

A fact to which Dr. Iles, of the Grant Smelting Works, and which it appears might be turned to account in correcting a slag, is the behavior of its metal under the magnet. Some slags are highly magnetic, while others are not. Would this not indicate that magnetic oxide is dissolved in the slag which has escaped reduction by ferrous oxide, and thus causes a waste of precious flux?

At the delinquent sale this week of the Ophir Mining Company 7,138 shares were sold for non-payment of the assessment. Of this amount about 3,500 shares were taken in by the company.

Averages in Mine Accidents.

Official statistics show that during the past fiscal year there has been a less number of deaths by accidents in the coal mines of Great Britain than before. This shows, too, that over a period of years the loss of life by accident in and about the mines has decreased, but the decrease is rather in proportion to the number of persons employed, and especially to the production of minerals from the mines, than in the actual number of lives lost. In the 20 years embracing 1861 to 1880 the average number of lives so lost was under 1,100; last year there were 46 under that number; but the number of persons employed and the tonnage of coal and other mineral raised have both been enormously increased, so that, though the number of lives actually lost is not greatly reduced, the safety in the mines in proportion to the employment afforded therein and to their yield is very greatly increased.

Last year there were 921 separate fatal accidents in these mines, as against 876 in the year 1882. The total loss of life is reported as 1,054 for the year 1883, and 1,126 for the previous year. There were 25 explosions of firedamp, with a loss of 134 lives, last year, as against 35, with a loss of 250 lives, in the previous year. But more lives were lost in consequence of falls of roofs and slides in the mines—469 last year, against 468 in the preceding year. The loss of life in the shafts of the mine was less—97 against 116; but the lives lost from explosions of powder, by machinery under ground, and other causes in the mine, rose from 208 for the year 1882 to 246 for the past year. The loss of life at the mines on the surface was also greater, the increase being due in part to a greater loss from machinery, the total loss of life on the surface being 108, instead of 84, as in the year 1882. There is, therefore, a considerable reduction in the loss of life from great mining accidents, but the loss from smaller and single accidents shows a slight increase on that of the previous year. The number of persons employed in and at the mines was, however, considerably increased during the year, the total being 10,000 more than in the year before, and thus, while in the year 1882 there was one death by accident for every 447 persons employed, last year there were 448 persons employed for every such death. This percentage of accidental death, though improved during the year, is still considerably above that in and about the metalliferous mines, which are separately reported on, in the same year.

Construction of Bratticings.

To divide a mining shaft a central "brattice" is used so that upcast and downcast air currents will result. For temporary purposes a brattice may be readily constructed as follows: "Buntions" as the English miners call them, are pieces of wood fixed across the shaft at intervals. These are generally two-inch stuff four or five inches wide. These are secured in any suitable way to the shaft timbers. One or two thicknesses of brattice cloth or painted canvas is nailed to the buntion and the brattice is complete at a small cost. Instead of the brattice cloth, ordinary inch plank nailed to the buntions can be used. The same kind of brattice, if required permanently, may be made of buntions three inches thick and five inches wide covered with two inch planks tongued and grooved, or having their joints covered with narrow slips one inch thick. But this costs twice as much as that first described.

One of the best forms of brattice is that known as the "plank brattice." It consists of a succession of three inch planks, placed across the shaft, buntion fashion, resting edge on edge, and kept in place by a double series of stringers. If the plank brattice is to be applied to a shaft lined with metal tubing, grooves for the reception of the planks may be cast in two rows of the tubing plate.

FOLLOWING are the latest observed temperatures in the Sutro tunnel: Tunnel entrance, air, 72; water, 111; shaft No. 1, east, 88; west, 96; shaft No. 2, east, 82; west, 52; shaft No. 3, 87; shaft No. 4, 75; Combination shaft connection, 65; Osbiston shaft connection, 100; C. & C. shaft connection, 81; Julia shaft connection, 99; Yellow Jacket shaft connection, 72; Forman shaft connection, 80. Flow of water in standard gallons, per day, 9,683,800.

Freezing Water in Mine Shafts.

Some little time since we gave an account of a system of freezing water in mine shafts. It was stated that the system was applicable in such places where quicksand existed, but its most particular utility was in sinking through water-bearing strata in shafts. A practical experiment is about to be made on the continent, in a difficult sinking. The system is called the Poetsch, after the inventor. The shaft has been carried down to a bed of quicksand, and in spite of persistent attempts to pass through it by means of piling, the efforts of sinkers have ended in failure. The work had actually been abandoned, when the representative of the Poetsch system offered to undertake the task. The offer was readily accepted, and the work was commenced without delay. Already the tubes have been put down, and the freezing apparatus will soon be in operation. This will be a severe test of the system, for the conditions are particularly unfavorable for its adoption. To take in hand a sinking that has already been carried down to the waterhead is to place the system at a great disadvantage. For want of space it cannot be worked in its entirety, and the operations of excavation are seriously impeded. This was the case in the first application. When the sinking is begun with the intention of applying Poetsch's system, as soon as the water-bearing stratum has been reached, it is to be laid out to the requisite dimensions. In such a case the inner and the outer row of freezing pipes may be properly placed, and there is room for the sinkers to work freely.

There was talk of this system being tried in England, but insular prejudices prevented a test. Mr. Andre, the gentleman who first called public attention to it, says numerous correspondents from this country wrote to him for information concerning the system, but in England no one paid any attention to it. This fact is cited by Mr. Andre as a sample of our "wide-awakeness," or a desire to be kept informed of all that is going on in the world, and especially of new inventions.

Bismuth.

There are a number of localities on this coast where bismuth is found. The usual ore is a sulphide. This ore is found in small quantities as a sulphide in a large proportion of the refractory ores of the Rocky mountains, and in considerable quantities in certain veins in Boulder and La Plata counties, Colorado. The production of metallic bismuth in the United States has thus far been of no importance. The ores, which in small quantities at least, are widely distributed in this country, give promise that in future the production of bismuth may become a regular industry. The metallurgical processes for the extraction of the metal from its various ores are quite simple.

The Tucson (Arizona) Index has been shown a grayish green impure oxide of bismuth, carrying about 8 per cent to 10 per cent, and found within a few miles of Tucson. There is no doubt that many of the so-called iron ledges are a bismuth oxide, of a grayish, greenish or yellow white color, often of an earthy nature, and would be called carthy ochreous varieties of iron. It is also associated with magnetite, and forms a carbonate incrustation on many iron ores. It exists as a sulphide in acicular crystals of a lead gray color. Telluride of bismuth has been found in two or three localities in Arizona. It is often found associated with gold, is of a steel gray color, and is both massive and granular. By the most simple and inexpensive tests the assayer can discover the presence of this metal.

THE California Commissioner to the New Orleans World's Fair, Colonel A. Andrews, will call together the Board of Trade, Chamber of Commerce and other organizations to devise means to raise funds for a proper display of the State's productions at New Orleans. He has received a letter from E. N. Burke, Director-General of the Exposition, in which that gentleman says he will recommend that the management of the Fair subscribe \$5,000 to that end. Colonel Andrews says \$15,000 more will be necessary to make a proper display.

PREPARATIONS are being made at Brandon, Coos county, Oregon, to destroy the sea-lions, which are a great detriment to the fishing interests on the Coquille.

Lower Wood River.

In the last number of the PRESS was given a map, showing the Upper Wood River mining region, Idaho, and we herewith present one which shows the Lower Wood River mining country, where most of the mining work is going on. The principal mining towns of the region—Ketchum, Hailey and Bellevue and their surroundings are here shown. So much can be said about the Wood River mines, that it is difficult to know where to begin. Ordinarily mining districts—at least the productive sections of them—are of limited extent and easily described. The paying properties are situated but a short distance from a given center; they can be enumerated on the fingers of one hand, and may be all visited in one day. Until the discovery of the great mineral belts of the Wood River country, Leadville was the only exception to this rule. In that famous region the mines were within a radius of a few miles, all located on the same body of mineral, or on spurs or shoots from it, and a description of one, except as to extent, would answer for the others. At Wood River, however, is an extent of mineralized country, which, as far as at present explored, is shown to be not less than seventy miles long, by nearly twenty in width, abounding in lead and silver, throughout its whole extent. Besides this mineral zone, which stretches from Bellevue to the Smoky, is another belt of similar, if not identical character, reaching from a point on Little Wood River, in the vicinity of Muldoon, to a point some miles northwesterly from Ketchum, a distance of perhaps fifty miles, where it unites with the first mentioned belt, forming an immense triangle. This second belt is of varying width from three to ten miles, and, in the opinion of competent judges, is in no degree inferior to the other.

There are a number of mines near Bellevue now being developed. Among the prominent ores are the Minnie Moore, Penobscot, Mammoth, Michigan and Star. The Ornament group is 10 miles west of Bellevue. The mines in the valley of Rock creek, and on the streams that lie west of it and flow into Camas creek, a tributary of Wood river, are gold bearing as well as rich in silver. On the east or Bellevue side of Wood river there are a number of promising mines on Lookout mountains. The town of Hailey is five miles north of Bellevue. On Croy creek, 7 miles west of Hailey is Bullion district, the principal mines of which are the Idahoan, Bullion, Jay Gould, Mayflower and Eureka.

Sixteen miles up Wood river from Hailey is the town of Ketchum, the central point of Warm Springs District. The district extends from Deer Creek on the south to Galena on the north, and comprises the mines on the East Fork of Wood river, Trail creek, Lake creek and Boulder creek, east of Wood river and Warm Springs creek, and the whole section of country west from Wood river to the Big and Little Smokies. The district is one of the most promising in Idaho, if not the foremost. The operation of the smelters of the Philadelphia Mining and Smelting Co., providing a market for the ores, has been one of its prime factors of success. We have from week to week been chronicling in our mining summary the doings at the various mines in that region, and it is not necessary to here enter into details. The whole region is a very rich and prosperous one. Large quantities of ore are shipped from here, and very many rich mines are being developed.

Concerning Ketchum and its surroundings, the *Keystone*, published at that place, has this to say:

"Ketchum is situated in the heart of the Wood River mining region, on a beautiful town-site plain at the confluence of the Trail creek and Warm Springs creek with Wood River. The town site borders the two latter streams, and is surrounded at distances of from a half to one mile by fine grazing hills and timbered mountains. The great Challis country is a tributary via Trail creek, the Sawtooth and Salmon regions of many mines via Wood River to the north, and the Warm Springs creek and Smoky regions via Warm Springs creek to the west. These several districts are all rich in mineral possessions, and present the brightest prospects for rapid development. Their only means of transportation is via Ketchum. The famous Elkhorn, Parker, Noonday and Baltimore mines, three miles east, the Irvine, Ontario, West Fork, and Black Horse several miles west, the Vienna,

Mountain King, Lyon, Solace, Emma, Silver King, Pilgrim, Lucky Boy and many others to the north, besides hundreds of smaller mines, and we dare say, thousands of prospects, all are tributary to, and dependent upon, Ketchum as a supply and transportation centre. Timber, water power, quarries, limestone, brick clay and everything calculated to encourage the building up of a flourishing city are here abundant, lending their inducements of economy in addition to the vast resources of mineral wealth of which we can be proud.

"Ketchum has the only smelting works on Wood River, and these, with a daily capacity of 180 tons will be enlarged as the time demands. We have a greater number of rich mines than any other vicinity. All those mentioned above as lying east, west or south are preparing to contribute largely to the local smelting works, while others are now keeping

with a heavy growth of pine, which interpose the most discouraging obstacles to the search for veins. The labor of prospecting has been so great, coupled with the shortness of the seasons, that it has nowhere, except in the immediate neighborhood of the best mines, received that careful study and scrutiny which has been devoted to other and poorer sections. Since the first year—when most of the discoveries were made by men on horseback—there have been comparatively few prospectors here. While the hardy class of men who find our mines are inured to toil, and are accustomed to all manner of privations incident to life in a wilderness, they shrink from a use of the pick and shovel when there is nothing but an indication in sight. In no other way will the wealth of these mountains be uncovered. An occasional accident brings the coveted ore to the light, but the country waits and waits intelli-

MAP OF LOWER WOOD RIVER, IDAHO.

stamp mills in operation in the Sawtooth country. The Elkhorn, Parker, Baltimore, Noonday, Ontario, Blackhorse and Irvine will probably be the largest shippers here this year. The Elkhorn alone netted \$50,000 in one month last season. We have much to expect from the East Fork of Wood river, six miles east, and from Greenhorn gulch, six miles west. These districts are new, but promising. The former is already famous for iron, having supplied the Philadelphia smelters with fluxes for two years."

In the last number of the *Wood River Times*, published at Hailey, is an article on the mines which gives a good general idea of the region: "In the early history of mining in Idaho the prospecting was exclusively for gold, and later, when the silver deposits in Owyhee county and some few other places were attracting attention, the hostility of the Indians who were roaming through the country effectively prevented its examination. Its great wealth, therefore, lay concealed from the world until the summer of 1833, since which time the prospector and miner have been almost daily bringing in proofs of its wonderful richness and unprecedented compass. Unfortunately, it is not an easy country to prospect. Everywhere it is covered with deep soil and detritus, and in many places

gent and diligent prospecting, and when it receives it it will astonish the most sanguine."

"In no other country in the world are the ores so rich as here. There are a few isolated instances of mines yielding richer ore, but comparison with such is unfair. Galena, which yields 120 ounces of silver has always been considered exceptional. There were 86 different mines which contributed ores to the Philadelphia Works the last two months of the past season and the average of them all was 143 ounces silver and 60 per cent lead. This result challenges comparison. The yield of the Leadville ores is, at present, less than 20 ounces. High freights and a fluctuating lead market are practically immaterial factors, but under the most adverse circumstances, the lead in our ores will pay for extraction, reduction and transportation, leaving the net yield in silver per ton still greater than that of any mining district in America. No place ever offered better inducements to mining men than this, whether they be rich or poor. A man with a hundred weight of ore can get its value with the same facility that a placer miner can sell an ounce of gold dust. The poor man with a claim which yields a little ore is as independent of capital as the farmer who subsists upon his own crops.

The Assessment Plan.

They are beginning to find out in Colorado and elsewhere, that the non-assessable plan of organizing and carrying on mining companies is not entirely what was claimed for it. They think now that what is known as the "California plan" of assessing people in proportion to the stock they own, has some good features after all. There are many good mining properties in Colorado, suffering from temporary embarrassment, which would now be working and perhaps making money for the owners, was their stock assessable. We tried this plan a long time ago in this State, and found it would not work. It was our experience which led us to adopt the assessment plan. There are defects in it of course. The main one is the freezing out process of continually assessing until small holders drop out. It takes time to levy and collect assessments and we do not have much of "freezing out" in these days. It is a good thing to be able to make every owner pay his share of the expenses or else sell out. As we have said the plan has been abused in some instances, but it is, nevertheless, the best that has been devised for developing mining properties. With stock forever non-assessable it is hard to get men to pay any money for having work done when the money paid for the stock is once spent. A few remarks of the *Colorado Mining Review* are to the point on the subject.

The plan of forming mining companies whose stock may become assessable is being talked of quite generally among those interested in the formation of new companies. Judging from the expression of opinions, we would not be surprised if quite a number of future corporations in Colorado, would organize under laws of States which are favorable to the assessment plan. While the non-assessable plan has prevented numerous swindles from being perpetrated by companies organized under Colorado laws, it has quite as often served as a bait to catch the ignorant with. The words "forever non-assessable," printed conspicuously on the face of certificates has been the ignis fatuus which lured many into heavy losses, who supposed that in making a purchase they were getting something that would yield a profit with only the trifling expense of the original cost. Although not fully advocating the assessable plan in all its features, there are many things about it which command our respect and attention. We have actually known of good mines lying idle and failing to receive the required annual assessment because of a refusal of the stockholders to pay for having it done. Under the non-assessable plan they could not be obliged to pay for it and hence, marvelous as it may seem, they would not do it, but allowed the property to pass into the possession of relocators. The Colorado law could be framed so as to permit persons to organize upon an assessable basis if they so chose. We venture to say that as much "freezing out" is practiced under the operation of one plan as the other.

Technical Training.

Ex-Governor Leland Stanford, President of the Central Pacific Railroad Company, has announced his intention of founding and endowing in this State an institution for free technical education. It is to constitute a monument to the memory of his only son, recently deceased. It is to be entirely independent of any other institution, and the founder hopes to establish it on a basis which will make it of a practical character, no higher education—as it is usually defined—being aimed at. To use the Governor's own words, "I propose that boys and girls—for it is to be for both sexes—who enter the institution, and who take a full course, shall when they come out know some business or trade so thoroughly that the question of bread and butter shall not be a stumbling-block to them on their entrance into life."

This indicates an intention to give the institution a broad scope and to confine it more particularly to industrial instruction. It has been within Governor Stanford's experience to have met many young men, highly educated, who knew no practical thing which would give them a living without gaining the experience at the expense of the employer. He wants to found a school which will give young persons some practical knowledge. He is now visiting the more prominent educational establishments in the East with a view of gaining information as to their practical workings. No more valuable donation to the people of California could be given than an institution of the kind proposed. With ripe judgment, abundant means and a desire to thoroughly accomplish his object in a practical way, Governor Stanford can do great good to the young people of this State, and we are glad to see him turn his wealth to so practical an account.

Borax.

No where in the United States have any considerable deposits of this valuable salt been found except in California and Nevada, where it occurs at a number of localities, in some of which it is found sufficiently concentrated to render them available for working. In some of the hot springs in the Yellowstone Valley, Montana, boracic acid forms occasionally as much as 6 per cent of the residue on evaporation, but generally the tenor is less than 1 per cent. The first discovery of this mineral in California is due to the late Dr. John A. Veatch, a close student and careful observer, who, as early as 1856, having detected the presence of boracic acid in the waters of certain mineral springs, followed up this clue, visiting many similar springs and various salines, until at last, after much search and many disappointments, he came upon quite a large deposit of borax resting in the bed and about the margin of a marsh or pond, situated on the easterly border of Clear Lake in Lake county, California.

The finding of this deposit was not the result of mere luck or accident, as has so often been the case in the discovery of valuable mineral deposits. Dr. Veatch, being thoroughly informed as to the conditions under which the salt is apt to occur in nature, after having his interest awakened by meeting with some traces of it in his travels, sought long and diligently for those peculiar salines which usually constitute its habitat. Many months were spent in going from one alkali flat or group of thermals to another before his researches were rewarded with even a partial success, for such, in the light of subsequent events, is all that can be claimed for this first find on the border of Clear Lake.

The more available portions of this deposit consisted of solid semi-opaque crystals imbedded in the mud at the bottom and around the edge of this pond, the mud itself and the marshy soil in the vicinity being also impregnated with borax, both in the form of minute crystals and as boracic acid. Only near the center of the pond, however, were the crystals found of large size and in great abundance. Here they occur to a depth of 10 feet in a tenacious blue clay, covered with a foot of softer mud. In this stratum of clay the crystals varied from a few grains to ten or twelve ounces in weight. Elsewhere they were found much smaller, the most of them being of microscopic fineness.

Following the Veatch discovery the California Borax Company was formed for working these deposits, the only material attempted to be utilized consisting of the larger crystals imbedded in the mud near the center of the lake. The method of operating employed by this company was as follows: The mud from the bottom of the pool was lifted by a dredging machine and emptied into large vats, through which a stream of water, raised by Chinese pumps, was kept constantly flowing. This stream, carrying off the mud, left only the large crystals, freed from all impurities, behind. The crystals thus obtained were then dissolved in boiling water, and afterwards recrystallized in lead-lined vessels, producing, without further manipulation, an article fit for the market. Although this was a most wasteful method of collecting the crude material, all the finer crystals and much boracic acid contained in the mud flowing back into the lake, the company found no economy in attempting to save it more closely. Had they not been misled on one or two vital points, the company would probably have worked their deposits more carefully than they did from the outset. In the first place they greatly overestimated the quantity of these larger crystals at the start; then too, these crystals, after the original crop had been removed, reproduced themselves much more slowly than had been expected. Between these two sources of error the company, as time wore on, found their stock of the crude material shortening at a rate which would eventually have forced them to curtail operations, an event that was precipitated by the heavy rains of 1866 and 1867, which so filled up the lake that but little was done thereafter. The discovery of the more prolific Nevada deposits a few years later so reduced the price of borax that the California company, soon after the mishap mentioned, ceased operations altogether, being unable to manufacture the salt at the low rates so brought about. During the period of their active existence this company produced about 300 tons of refined borax annually, which was sold in San Francisco at an average of 25 cents per pound.

The Principal Borate Fields of Nevada.

The borate fields are situated in the extension salines known as Teel's marsh, Rhodes' marsh, the Columbus marsh and Fish Lake valley, all in the south-easterly part of Esmeralda county. These salines consist of oval-shaped alkali flats occupying the centers of immense basins, and cover from 10,000 to 20,000 acres each. These basins are surrounded for the most part by a broad margin of sage plains which rise gradually to the base of the hills and mountains which enclose them on every hand. They have no outlets, and, receiving the drainage of the country around, retain everything brought into them, including the borates and other salts of various kinds. From midsummer till late in the spring, when the snow commences to melt on the mountains, these saliniferous lands are, as a general thing, apt to be dry,

only shallow lakes occupying sometimes their points of greatest depression. At other seasons of the year portions of them are covered with water to the depth of a foot or two. Heavy rains, though these seldom occur in this region, convert these alkali flats into beds of tenacious mud, even a slight shower rendering their passage by teams difficult for the time being. Water can be obtained on these salines almost anywhere by digging from 2 or 3 to 10 or 15 feet below the surface. It is generally brackish, however, often so much so as to be unfit for drinking. By digging to much greater depth good water is obtained a short distance back from the edge of the marsh. Over large sections of these flats exist deposits of common salt, carbonate of soda and borax. This latter mineral does not however, occur here as at Clear Lake, California, in the shape of compact, semi-opaque crystals inclosed in mud, but generally in the form of borate of lime or soda. The former is found at many spots imbedded in these marshes from one to four feet below the surface. It crystallizes in long, silky fibres which gather into balls from an eighth of an inch to 2 or 3 inches in diameter. These globular masses have the lustre of white satin, and when dug up readily separate from the enclosing earth. The borate of soda mixed with sand and other impurities, accumulated on the surface in the shape of a dark colored incrustation an inch or two thick. This crust when dry, being hard and brittle, can be easily detached from the moister ground beneath and broken into fragments.

Fish Lake Marsh.

This is the most southeasterly saline of this group, and covers an area of some 10,000 acres, occupying the center of a basin three times as large. Commencing at the northern end of this marsh, or, rather, alkali flat, we come first upon a cluster of small mounds covered with a white incrustation from 6 to 8 inches thick, and carrying about 20 per cent boracic acid and 45 per cent of other soluble salt, the surface soil in this portion of the flat being also slightly charged with similar substances to the depth of several feet. A good deal of the crude material could be, and, in fact, has been collected here without much labor. A little further on is found a patch of nearly 100 acres covered with an efflorescence of the various salts—borates included—and which, being moist, flaky, and of a dazzling whiteness, might easily be taken for fallen snow, the illusion being strengthened by the manner in which this stuff can be compressed into balls that harden, still retaining their forms after the moisture escapes. At this spot the borates mixed with the chloride of sodium, soil and other impurities can be gathered up without much trouble.

Proceeding south, a patch of forty or fifty acres is crossed, when the borates of lime and soda lie on the surface, but so mingled with the grass, roots and earth that much worthless stuff would have to be taken up in the process of gathering them. This, when attempted, is usually done with a broad wooden hoe. Continuing in this direction, we arrive successively at several large tracts, the whole embracing 400 or 500 acres, where the borates occur, either in the form of an efflorescence on the surface or imbedded in the ground. On some parts of these tracts, and over large areas outside of them a thin crust of borate of soda covers the surface; the most of it, however, is too low-grade to be of present value. Scattered over this saline are numerous small spots, rich in the borate of lime, and from which a good deal of this material has already been taken. What is here said of the borate deposits in Fish Lake valley will apply largely to those elsewhere in the great Utah basin, to which they are mostly confined, the general features of these salines being much alike. This valley is, however, marked by this peculiarity. It contains several thousand acres of good farming land and natural meadows, whereas the other marshes are wholly barren. This exceptional fertility is due to a number of small creeks, which, flowing from the mountains, make their way out into the middle of the flat. Aided by artificial irrigation, fair crops of grain and vegetables are raised on this land.

The Columbus Marsh.

This lies 12 miles north of Fish lake, with which it is connected by a narrow valley. While a large portion of this marsh is covered with a thin crust of common salt, it affords but comparatively little borate of soda. At its lower and northerly end, however, when the drainage has brought in and left the various salts leached from the immense watershed around it, a heavy bed of borate of lime has been formed. During the dry season this deposit, through accumulations of the salt coming up from below, suffers marked enlargement, swelling up as if undergoing a process of fermentation. With the advent of wet weather, the moisture dissolving and scattering the salt, the mass suffers a corresponding shrinkage. Under a bed of clay about two feet thick a layer of sulphate of soda occurs, beneath which come in alternate strata of clay and sand, both barren of the borates or other valuable minerals. In 1872 the Pacific Borax Company put up a refinery here, at which a good deal of marketable borax was afterwards made. At a later period the company transferred these works to Fish Lake valley, where they have since been operated for a good portion of the time.

Rhodes' Marsh.

This marsh is located twelve miles northwest from the Columbus marsh, the mineral deposits

of both salt and borax at these two places being much alike. Rhodes' marsh is at all times quite soft, the water coming within a foot or two of the surface, and in wet weather covering the most of it to a depth of a few inches. At the works of the Nevada Salt and Borax Company erected here, about one ton of refined borax is made daily. The method employed in manufacturing the salt is as follows: The crude material as collected from the marsh is placed in large receivers and is there dissolved with steam, after which the mass is run into galvanized iron tanks, inside of which are suspended plates of like metal. Here the borax crystallizes on the surface of the iron, a process which is effected in about six days. When completed, the fluid is drawn off with syphons, after which the crystals are removed and packed for market. With some slight variations, the method of manufacture here in use is the one adopted by the other companies.

Besides borax, the company collect here a good deal of common salt, the best of which is ground for table use, the more impure being disposed of to the silver reduction works in the neighborhood.

Teel's Marsh.

Situated 15 miles south of the town of Columbus, is owned by Messrs. Smith Bros., who have put up on the spot a capacious refinery. The deposits here, which are very extensive, have been largely utilized, the aggregate production of these works exceeding that made by any other in the State.

Other Borax Marshes in Nevada.

Several other marshes exist at other and widely separated points in Nevada. One of these is located near Sand Springs, Churchill county, distant from Columbus over 100 miles. Here a refinery was put up by the American Company in 1870. It contained six tanks, holding 2,000 gallons each, and had a capacity to make one ton of borax daily. These Sand Springs deposits, however, proved to be of such low grade that the company gave up the business after continuing it at a loss for several years. At the Hot Springs, 50 miles farther to the northwest in the same county, occurs another and similar deposit of the borates, and at which a like attempt was made a few years later with like results reached at Sand Springs. In the region of the Mud lakes, in the north-western part of the State, extensive beds of the borates are reported, though nothing definite is known as to their fertility. They will need to be rich to warrant any effort being made at working them, as this will involve the necessity of wagon transportation for nearly 100 miles over an absolute desert.

Besides these marshes, in which this salt occurs in the form of mineralized earths, the waters of certain lakes and springs in different parts of the State have been found to contain a notable percentage of boracic acid. One of these lakes, in the vicinity of Ragtown, Churchill county, was the site of the pioneer enterprise in this branch of production in Nevada. Here, as much as 15 years ago, the manufacture of borax was essayed through the plan of pumping up the water and carrying it out on the adjacent alkali flat, and there leaving it exposed to solar evaporation, which process it was expected would proceed with sufficient rapidity to render the undertaking profitable. But in this there was disappointment, and the scheme, otherwise radically defective, met with early abandonment, the projectors losing much money and producing very little borax.

Russian Mines.

Some idea may be formed of the extent of the possessions attached to the Russian crown when it is stated that the Altai States alone, in which are situated the gold and silver mines of Barni, Panlov, Smijov and Loktjepp, the copper foundry at Sasonn, and the great iron works of Gavrilov, in the Salagirov district, cover an area of over 170,000 square miles, being about three times the size of England and Wales. The receipts from these enormous estates are in a ridiculously pitiful ratio to their extent. In the year 1882 they amounted to 950,000 roubles, or a little more than £45,000; while for 1883 the revenue was estimated at less than half this sum, or about 400,000 roubles. The rents, etc., gave a surplus over expense of administration of about a million and a half of roubles. On the other hand, the working of the mines showed a deficit of over a million; hence the result just indicated. A partial explanation of this very unsatisfactory state of things is to be found in the situation of the mines, which are generally in places quite destitute of wood, while the smelting works are naturally located in districts where wood abounds, sometimes as much as 400 to 500 miles distant from the mines. The cost of transport of raw materials became considerable in this way. By degrees all the wood available in the neighborhood of the smelting works became used up, and it was necessary to fetch wood from distances of over sixty miles. Formerly the mines were really penal settlements, worked by convicts, who were partly helped by immigrants whose sons were exempted from military services on the condition of working in the mines. But since the abolition of serfdom this system has been quite altered, and there is now a great deal of free labor on the ordinary conditions.

Mining Resources of El Dorado County.

It is well known that El Dorado county was, for a number of years, the banner placer diggings county; her product of gold running up into millions upon millions annually. These rich diggings were not confined to any special locality, but extended clear across the county, and the belt, in width, ranged from twenty to forty miles. In those days nothing but surface and river diggings were known, and when the cream had been partially worked off, so that a miner, with the crude facilities then in vogue, could not make over ten or fifteen dollars a day, the claim was abandoned and fresher and more inviting fields sought. Later on these abandoned claims were re-located and worked as long as they would pay from six to ten dollars per day, and then sold or abandoned again. Later on these were again re-located, and with improved methods and appliances, were made to yield handsomely; and so it has gone on up to the present day, until there is now very little surface ground left that can be profitably worked. But we have yet unlimited deep gravel deposits that are rich in gold, as well as untold rich quartz veins, which have already been made to give up many millions in treasure. These require capital to develop, in most instances, though occasionally mines have been made to pay right from the grass roots down, the pay increasing with depth. Enough money has been squandered in the attempted development of some of these mines, through incompetence, mismanagement and dishonesty, to have opened and thoroughly developed a hundred or more good paying quartz and gravel mines, had the money been properly applied. As it is, we have to-day but comparatively few good paying mines, and they are in the hands of private individuals or close corporations, and little is said or known about them, beyond the knowledge that they are good paying properties.

We have a number of partially developed quartz mines that, for the work done, promise well. Some are tied up because of quarrels among owners, some for want of means to proceed further with development, and others are held for a sale at large figures, while the development is not sufficient, as a rule, to warrant paying prices demanded.

If capitalists would, instead of paying high prices for shafts and tunnels with indifferent prospects, purchase a few undeveloped, or partially prospected mines, or hold them, have them economically and intelligently tested by practical miners, instead of sending some impractical squirt, with Col. or General prefixed to his name, from New York or Boston, to superintend them, and fool away the money intended for legitimate work, they would be sure to get an occasional good mine at much less expense than has been their usual experience.

Grizzly Flat, some twenty miles east of Placerville, is to-day a more promising field for the judicious investment of capital in legitimate mining than can be found in the same extent of territory anywhere else in the State, and but two or three years at least can elapse, even with present progress, before capitalists will be astonished that they did not sooner recognize the wealth of that locality, and secure a goodly share when it could be had at nominal figures. Of course every prospect hole does not constitute a mine, but good mines are discovered by first sinking prospect holes, and developing only those that prospect well; but, unfortunately, too much money has heretofore been lavished upon insignificant prospects all over the county—in some instances with a view to catching gudgeons, and realizing handsomely, which, in a number of instances, has proved a success, but to the detriment of our best mining interests, as it has given quartz mining, to a great extent, a black eye with those who do not fully understand the situation. But this matter is becoming better understood, and we are confident that it will not be long before a tide will set in that will fully demonstrate the fact that we have as good quartz mines, and more of them, as are to be found anywhere in the world.

In the immediate vicinity of Placerville, at no distant day, a dozen good quartz and gravel mines will be developed and operated, which, together with the deep gravel belt in its entire extent, will give employment to at least a thousand miners. The north side of the county is also as fair a field for the development of good mines as is to be met with anywhere on the coast, but considerable capital, hard work and good judgment is required to open them up, and this is necessary in any enterprise of similar magnitude. South of Placerville, also, there are some excellent mines, and numerous flattering prospects for many more. This interest is as yet really in its infancy, but can remain so but a short time now, as the fact is becoming so generally known that what we have claimed for years is a veritable fact, that our mineral belt is teeming with hidden treasure. The enormous quantities already secured, the good and permanent mines now developed and working in all directions, and the large extent of country open to prospect and development, all clearly point in this direction.—*Placerville Observer.*

THE mineral belt in Sweetwater district extends from seven to eight miles north and south, and is about two miles wide. It is in porphyry, mixed with felspar overlying syenite on the west. It is a somewhat curious fact that all the lodes on the east dip to the west, while those on the west dip to the east.

ENGINEERING NOTES.

Great Bridges.

The new bridge across the Firth of Forth, now building, will, when completed, be among the most remarkable bridges in the world. The main girder will be within a few feet of a mile in length, and will rest upon round cylindrical piers, each of which will weigh 16,000 tons. It will, of course, be high enough for all vessels to pass underneath, and about 42,000 tons of steel will be required in its construction. The estimated cost will be \$7,500,000.

China possesses the longest bridge in the world. It is at Lungang, over an arm of the China sea, and is five miles long, 70 feet high, with a roadway 70 feet wide, and has 300 arches. The parapet is a balustrade, and each of the pillars, which are 75 feet apart, supports a pedestal on which is placed a lion, 21 feet long, made of one block of marble.

The highest bridge in the world is said to be the railway viaduct at Garabie, in France, now being erected over a river in the Department of Cantal. The bridge has a total length of about 1,800 feet, and near the middle of the great center arch, which is one of the noteworthy features of the structure, the height from the bed of the river to the rail is 413 feet.

The Erie railway bridge at Kinzua, near Bradford, Pa., is also an astonishing. The greatest elevation of the bridge (301 feet) is 18 feet higher than the spire of the Trinity Church. 24 feet higher than the summit of the Brooklyn bridge towers above high water, 143 feet higher than their elevation above the roadway, and 82 feet higher than Bunker Hill monument. The bridge is 2,052 feet long.

The Brooklyn bridge is 5,989 feet long; clear height in center of river span, 135 feet; length of river span, the longest span in the world, 1,595 feet. *Ex.*

SANITARY ENGINEERING. The Massachusetts Institute of Technology has under consideration a proposition to establish a course, especially for the training of men to combine something of the architect, the civil engineer, the chemist and health officer. The problems of house drainage, water supply, sewerage for cities and towns, dwelling and factory construction, and general sanitary regulations are to be given special attention in connection with the usual course in civil engineering. It is not probable that any great number could find speedy employment or business in this specialty, but the fact that a leading technical school is seriously contemplating the introduction of sanitary engineering as a feature of its curriculum indicates that there is a pretty strong pressure, if not a positive demand, for men educated in this direction.

ANOTHER BIG BRIDGE.—It is reported from Russia that the question is being agitated of connecting Cronstadt and Oranienbaum by a bridge, at a cost of about \$12,000,000. The structure will be erected under the supervision of engineers appointed by the Russian Government. It will rest upon granite pillars, fixed by the caisson method, each of them protected from the action of the waves during the prevalence of southwest winds by an angular wall-like guard of stone. The bridge will be about five miles in length, and it is expected to be completed in the year 1889. When finished it will consist of two parts—a railway and a foot-bridge and will be illuminated by the electric light.

A DOUBLE CABLE ROAD.—They are about to introduce the San Francisco system of cable roads into Kansas City, but with this difference: This will be the first railway of the kind that will be provided with an extra cable, the second cable to be used only in case of breakage or other disability of the first cable. The delays and annoyances from the breakage of cables, especially in new roads, where green hands have to be broken in, are very vexatious, and should be provided against if practicable at a reasonable cost.

CAPTAIN EADS is now busily engaged in London with a corps of draftsmen and engineers preparing a complete set of new models to illustrate his proposed ship railway across the Isthmus of Tehuantepec. It is understood that a number of prominent English engineers have manifested considerable interest in the project, and that in the course of a few months some negotiations will be entered into which are expected to give the enterprise a definite shape.

THE COMMERCE of the seas is carried on by about 12,000 steamers and more than 100,000 sailing vessels, while the railroad traffic of the world employs about 66,000 locomotive engines and 120,000 passenger and 500,000 freight cars. There are 200,000 miles of track, and the capital invested is \$20,000,000,000.

AN elevated passenger railroad, extending some 10 miles from the Delaware to the western limits of Philadelphia, and costing \$8,000,000, is projected, and said to stand a fair chance of being built. Its principal route would be through a narrow thoroughfare called Cherry street.

CAPE COD CANAL.—Work on the Cape Cod Canal is progressing, with an energy which shows that the present projectors are in earnest, and intend to complete the work at an early day.

USEFUL INFORMATION.

Birch Oil.

Birch oil is a new product which is coming into notice. A contemporary gives the following as a simple and cheap process for its manufacture: "The apparatus consists of a furnace, a boiler, a tin pipe, a trough into which water is continuously brought from a mountain brook, a barrel and a glass jar. The furnace is made of loose stones, so arranged that the fuel is put in at one end and the smoke goes out at the other through an old piece of stovepipe. Over the furnace is the boiler, which is merely a wooden box about three feet wide, four long and three deep, with the bottom covered with sheet iron to prevent burning. The boiler has a wooden lid, so that it can be tightly closed, and from the top leads the tin pipe. This pipe runs into the water trough and through it, so that the water always surrounds and cools it. The end of the pipe, after coming out of the trough, opens over a barrel, and in this barrel, exactly under the end of the pipe, is placed the glass jar. This constitutes all the plant."

The boiler is filled about a third deep with water; the birch bark and twigs are shoveled in until it is full; the lid is placed, and the fire started in the furnace. For hours the fire must be carefully watched, and fresh fuel continually furnished. The material in the boiler becomes heated, the oil in the twigs extracted and mixed with the water. At boiling heat, the steam arising from the water and oil passes through the tin pipe and becomes chilled by the water in the trough; a condensed liquid is the result; and this mixture of oil and water escapes from the pipe, when it naturally separates. It drips into a glass jar placed over a barrel; the heavy oil sinks to the bottom of the jar, while the water flows over and is saved in the barrel, to be again reboiled the next day. The oily substance saved in the jar is the oil "pure and undefiled."

STREET DANGERS INCREASING. The dangers of the streets increase with advancing civilization. A New York Juvenal would have many perils to notice in addition to those which he has described as threatening the pedestrian in the streets of Rome. The employment of the electric light in the city just mentioned has already produced several serious accidents. The latest recorded was by the breaking of a telephone wire, which fell upon an arc light wire, deflecting from it a portion of the day current. A team of horses drawing a coal cart arrived just in time for the fallen wire to drop on them. The horse on which it first rested stopped instantly, trembled violently and then dropped to the ground, kicking convulsively. As he fell the wire came in contact with the second horse, and with exactly the same results. The driver sprang from his seat in the cart and recognizing the wire as the cause of the accident, he took hold of it to pull it off the horses. Those who saw the incident say he did not hold it the millionth part of a second, when he dropped it with a terrific yell, and he remained speechless and unconscious for some time. Fortunately no life was lost; but if the accident had occurred at night, while the full current was passing through the wire, the man and the horses would doubtless have been killed. —*St. James Gazette.*

DIGGING WELLS.—The old way of digging a well and stoning it up so as to leave it about three feet in diameter, is a very good one where the well is to be left open and the water drawn up with a bucket; but a very poor one if it is to be covered and the water raised with a pump. If covered, a large space is left for dead air, which often affects the character of the water, and makes it unsafe to enter the well. When thus stoned up and a pump used, the covering should be at or near the water. But if a pump is to be used the better way is to save the cost of stoning—dig the well in a dry time, and put in a cement pipe, after a sufficient quantity of water has been reached, and continue the pipe to the surface, filling up the well outside the pipe. The pipe should be covered, but the quantity of air confined will be small, and as the well cannot be entered no danger will arise from that source.

TO BRONZE IRON OR STEEL.—A German technical journal gives the following method of producing a bronze-like surface on iron or steel, which prevents rust: The object to be acted upon must be cleaned so as to take off all oxidation or other impurity. It is then exposed for two or three minutes to the action of the vapors of a heated mixture of hydrochloric acid and nitric acid in equal portions, at a temperature ranging from 550 to 650 degrees Fahr. After the objects have cooled, they are to be rubbed over with vaseline, and again heated until the vaseline begins to decompose. This treatment with the vaseline has to be repeated once. Should a lighter coloring than bronze be desired, it can be produced by mixing acetic acid with the other acids.

WHAT THE ZERO MARK MEANS.—Ninety-nine citizens out of a hundred had something to say about "zero" yesterday; perhaps not one in a hundred could have told off hand why a point thirty-two degrees below the freezing point on Fahrenheit's thermometer is called zero. For that matter, nobody knows. The Fahrenheit

scale was introduced in 1720. Like other thermometric scales, it has two fixed points the freezing point, or rather the melting point of ice, and the boiling point of water. The Centigrade and Reaumur scales call the freezing point zero, and measure therefrom in both directions. This is a very natural arrangement. Fahrenheit kept the principle on which he graduated his thermometers a secret, and no one has ever discovered it. It is supposed, however, that he considered his zero—thirty-two degrees below freezing—the point of absolute cold or absence of all heat, either because being about the temperature of melting salt and snow, it was the greatest degree of cold that he could produce artificially, or because it was the lowest natural temperature of which he could find any record. The grounds on which Fahrenheit put 180 degrees between the freezing and boiling points are likewise unknown.

COTTON BELTING.—An advocate of cotton belts says: "Woven belts give and take. This is in the nature of a woven material. When first put on, they require 'taking up' once or twice more than leather. The stretch is approximately six per cent as against four per cent in leather; but once well at work, they give less trouble as there is but one joint to take after. If put on really tight enough, this stretching is diminished to a great extent. Users are afraid to overstrain the belt, but the extraordinary result attained by certain experiments made as to tensile strain, shows the impossibility of breaking a belt under fair conditions."

GEYSERS AND SPRINGS IN THE YELLOWSTONE PARK.—The latest scientific explorations of the Yellowstone Park, made during the past summer by members of the United States Geological Survey, show that it contains 500 geysers and 5,000 hot springs. These numbers are somewhat larger than those obtained in earlier surveys.

DEEP DRIVE WELLS.—At Norwich, England, a drive well has been put down to a depth of 157 feet, and might have been driven deeper if required. The tube was two inches internal diameter. At Montreal, Canada, a drive well tube has been driven 174 feet.

COLORS IN THE ELECTRIC LIGHT.—The employment of the electric light is impracticable for many purposes, because it fades colors as effectually as sunlight.

GOOD HEALTH.

Elevated Railways Cause Eye Troubles.

The introduction of the elevated railway into the streets of New York, says the *Scientific American*, has also brought in a peculiar class of optical troubles, due to the lodgment of iron dust in the eyes of pedestrians and others who have occasion to travel or pass under the railway structures. Hundreds of such cases are now treated at the hospitals, and most of them are successfully cured, the particles being removed by a gouge-shaped instrument about the size of a sewing needle. The pieces are too firmly held to be removed by magnets.

The trains have a high speed between stations, and are quickly brought to a stop. This requires strong braking, which grinds off the iron from the shoes in fine showers, and the iron particles fly in all directions.

A magnet applied to the tops of the cross ties attracted a large quantity of very fine iron dust. Each passing train deposits its quota of iron, not only on the cross ties, but upon the street below. * * * These particles varied in size from one-sixteenth of an inch to dust so fine as hardly to be distinguished by the naked eye, and were frequently entirely invisible, requiring the aid of the microscope to reveal them. Viewed under the microscope, their dangerous character becomes apparent. The greater part were bordered by a jagged fringe with very fine points, compared with which the point of a cambric needle appeared dull. Not infrequently the projections were hook-shaped and barbed similar to a fish hook, which will account for the difficulty experienced in removing them from the eye, into which they have been driven—the closing of the eyelid and the rubbing which thoughtlessly followed, assisting to more firmly imbed them in the cornea.

In order to determine whether iron particles could be attracted while floating in the air, a magnet exposing about one square foot of surface was suspended in mid air under one of the railroad tracks, and although the magnet was by no means a strong one, it attracted to itself iron particles in spite of a strong wind which blew at the time.

Further, the awnings of shop keepers along the lines of the elevated railroad are discolored by iron rust in a very short time, and require frequent renewals, since washing fails to remove the stains which the rust produces.

The evil above described being manifest, the question of its prevention naturally suggests itself. The subject is worthy the attention of inventors.

OILY SKIN.—In some persons there is an excessive production of sebaceous matter or sebum, due to morbid activity of the fatty glands of the skin. The skin of such persons presents a shiny look. Little beads of oily matter may be seen at the mouth of the glands near the roots

of the hairs. The forehead, nose and cheeks are most frequently affected. When the scalp is affected, the condition may be indicated by soiling of the pillow. Acne is frequently accompanied by this condition. Treatment.—The only treatment to be employed is the frequent application of soap. When many of the glands are clogged up, as indicated by the abundance of grubs, the surface should first be thoroughly rubbed with warm oil. Coconut or almond oil is the best. After half an hour the surface should be rubbed with a flannel cloth, thoroughly saturated with soap moistened with warm water, and stretched over the fingers, or a soft sponge may be used. This is best done at night, just before retiring. When the secretion of fat is very profuse, the operation may be repeated two or three times a day. —*Good Health.*

AN ENGLISH COUGH REMEDY. One of our English contemporaries, in reply to an inquirer, recommends a syrup made of the following ingredients for colds and coughs: Take 18 ounces of perfectly sound onions, and after removing rind make several incisions, but not too deep. Boil together with 13½ ounces of moist sugar and 2½ ounces of honey in 35 ounces of water, for three-quarters of an hour; strain, and fill into bottles for use. Give one tablespoonful of this mixture (slightly warmed) immediately on attack, and then, according to requirement, five to eight half-tablespoonfuls daily. It is said that this recipe was that used by the Zulu Caffres when visiting Europe some two years since, and who suffered much from the climate, but invariably recovered upon its use.

FOOD AND NUTRITION.—So long as men exist there will doubtless be one, occasionally, says the *Mechanical Engineer*, who will obligingly figure out for us the amount of nutriment contained in certain kinds of food. This is a harmless amusement, and as useless as harmless. What does it matter how much nutriment is contained in this or that edible? Very little, for it is that which one's system is able to assimilate, or take up, which strengthens, not the quality which passes into or through it. Savors assist deglutition quite as much as more nutritious food. There is no danger that mankind will not get enough nourishment; the trouble is in the opposite direction usually.

A REMARKABLE CASE OF TRANCE.—A case of trance has lately ended in Glasgow. A woman thirty-five years of age has lain since June last in a state of coma, motionless, with closed eyes, a pulse of about eighty per minute, natural temperature, and normal breathing. Consciousness was entirely absent until, at the end of November, she suddenly awoke, and is now recovering her wonted strength. During her long sleep she was fed daily by a stomach tube. The case is well-nigh unique on account of its duration. These trances are the puzzle of the physiologists, and simulate death so closely that patients have been in danger of burial alive.

SHERRY AND CIDER.—Liebig, an authority in matters of health and things which are good to eat and drink, thus wrote: "Sherry and strong cider are more quickly intoxicating than the generality of wines, and they have a peculiar influence on the gastric juices of the stomach. The intoxication of beer is heavy and dull, but its use does not bind the drinker from gaining flesh. The drinkers of whiskey and brandy are going to certain death. Red wine is the least hurtful, and in some cases really beneficial."

BIRDS AND EPIDEMICS.—There is a good deal of testimony to prove that birds and insects disappear from localities about to be affected with epidemic disease. More attention should be paid by medical men to the collection of meteorological information and collateral data during the prevalence of epidemics. It is nearly a virgin field for scientists.

HUMAN SKIN and the skin of young rabbits have been successfully applied in small pieces to large healing surfaces in wounds. Dr. Wilson, however, according to the *Medical News*, claims to have obtained very much better results from the use of the internal membrane of hen's eggs. The eggs should be fresh and warm—warm from natural heat.

HOT MILK AS A RESTORATIVE.—A writer in the *Medical Times and Gazette* recommends the use of hot milk as a restorative. Milk, when heated above 100 degrees F., loses its sweetness and density, but has a most beneficial influence over mind and body when exhausted by labor or mental strain. Its effects are more invigorating and enduring than those of alcoholic stimulants.

HOT LEMONADE FOR DIARRHŒA.—Some people prefer hot lemonade to the usual form, but it is only recently that we have seen it recommended in diarrhœa. Dr. Vigouroux recommends a glass of hot lemonade every hour, or half hour, as an easy, agreeable and efficient treatment for diarrhœa.

Hot milk is an excellent food for consumptives. From four to eight glasses should be taken daily. The evidences of benefit are increase in weight and strength, lessened cough, and checking of bowel looseness.

CHARCOAL POUULTICE.—Sprinkle fresh, finely powdered charcoal over a bread and milk poultice in a thin layer, and apply as usual.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

SUTTER CREEK.—Cor. Amador Ledger, May 24: Work is still going on at the Lincoln mine. There are three or four men on contract, and hopes are entertained of striking something before long. The Con. Amador mine, according to current reports, is on the improve. An improvement in the quality of rock has been noticeable in the last week or two. The Company is paying off this week. W. A. Woodworth has started an eight-mule team to haul a few timbers for the Mahoney mine. He is under engagement for the summer to haul timbers for the Keystone mine. Strickland, McKean and Hughes, who have been running on hydraulic claim about six miles above here closed operations last week on account of the shortness of water. The cleanup was up to all expectations, and there is ground enough to keep them going for years to come. During the summer they will devote their attention to burning coal, etc.

NOTES.—Amador Ledger, May 24: The gravel claim of the McKee Brothers, at American Flat, Oleta, was cleaned up a short time ago. The season's run was about three months, and we are told the amount taken out was \$1,200—considered a satisfactory result. S. H. Loree is engaged in cleaning up his hydraulic claim at upper Rancheria. The gravel claim of Hadley & Vair at Upper Rancheria is running full blast, with flattering prospects. At the S. Julien quartz mine, Middle Bar, connection has been made with the surface at the end of the tunnel by upraising until an old abandoned tunnel has been tapped. The ventilation has been much improved thereby. On Tuesday a new body of rich quartz was struck, said to be over two ft. wide. The mill had been running on slate for a week previous, but was started on the new ore-body last Wednesday. The new concentrator just rigged up for test purposes by Judge Reed, of Jackson, is in full operation and works charmingly. It bids fair to prove a very valuable invention, and we shall give a full description of it at an early date. The Mahoney pump broke Tuesday, after getting the water down to within 20 ft. of the bottom. The break will necessitate a period of idleness for three or four days during which the water will rise considerably. It is probable, however, that next week will see the bottom of the shaft. The big tunnel at Middle Bar is in over 9,000 ft. The present contract for 1,000 ft. is expected to be completed within two weeks. A blower is on the ground, and will be in running order in a few days. R. B. Reed and W. B. Vandemant, owners of the St. Louis mine, near Clinton, are crushing rock by arrastra process. They have a tunnel run about 100 ft into the hill, and have struck the ledge at 100 ft from the surface. The ledge is from three to four ft wide, and has paid an average of \$60 per ton. They can only crush about half a ton per day, and are not prepared to work on a larger scale until they get it more fully opened up. The Matson mill near Butte was started this week on rock from W. E. Stewart's claim near Big Bar.

El Dorado.

REVENGE.—Georgetown Gazette: We learn that work preparatory to starting up the Revenge mine near Greenwood is being pushed forward with much energy, under Superintendent Dixon. A force of mechanics consisting of D. W. C. Benjamin, Milo Knox and Fred Smeder have just completed the boarding house, and now begin the work of putting up a fine five-stamp mill.

Mariposa.

HORNITOS.—Mariposa Herald: The No. 9 mill has been running the past week. Mr. Huling is on his way here from the East, and as soon as he arrives work will be resumed on his numerous mines, which have been flooded during the winter.

Mono.

LUNDY.—Homer Mining Index, May 24: The Bryant mine was practically the first on which operations were begun this season, and as it has in sight a large quantity of high grade ore, negotiations are now pending for a mill. Forty-nine tons of ore taken from the 130 level of this mine last Autumn, and hurriedly worked in the primitive two-stamp mill in Lake canyon, yielded \$2,937, or within a fraction of \$50 per ton. The 201 feet of drifting along the vein on the 130 level shows a uniform thickness of two ft of ore of the same quality, the fissure itself being much wider, but materially filled, at that level, with other vein matter. James McDonald, one of the owners, is at present in charge of the work, and Hon. P. Reddy, who is also a large owner in this valuable property, is expected here at an early day to consult as to the best plan of opening and working the mine on a comprehensive scale. The greatest activity prevails about the May Lundy property—mine, mill, tramway and wagon road. The mill is being thoroughly overhauled and put in readiness for the additional five stamps, which are expected here every day, and which will be planted as an eastern extension of the other batteries. Large numbers of men are strung along the whole length of the road from the mill to the foot of the tramway, and the road would have been cleared for the passage of teams by Monday next but for the interference of rain storms during the week. The mine has been cleared for action, and the working force underground is still being steadily increased. The winter's damage to the tramway is also being repaired, and it is expected that the ore teams will be put on the road about the 2d proximo. Reports reach us that very favorable indications are being met with in the Great Sierra Tunnel in Tioga district. The country rock is now said to be unusually soft, full of stringers of quartz and saturated with water. Nothing has been heard lately about the resumption of work on the Detroit copper mines in Jordan district. A snow slide carried away 250 to 260 ft of the tramway during the winter. The Gorilla mine has been put in excellent condition for the extraction of ore, and manager Winterhalter is expected here the coming week to start up work on a larger scale. Supt. D. E. Jones was expected at Jonesburrow yesterday, and will doubtless start up the Virginia creek hydraulic next week. Over at Mount Raymond the snow is said to be still 25 ft deep, and it will be late

in the season before any work can be done at the mines.

Nevada.

THE NORWAY MINE.—Nevada Transcript, May 24: Dr. Buelow returned this week from a trip to the Norway mine on Canyon creek seven miles above the town of Washington. Seven men are at work there, and he found the developments to be most encouraging. The ledge is two and a half ft thick in the lower tunnel (which gives 2,000 ft of backs), and the samples of ore the doctor brought down with him are very rich in free gold. Quartz is being taken out regularly, and the mill will be started in a week or ten days.

BROKE A PUMP ROD.—Grass Valley Union, May 23: The rod of the 8-inch pump in use in the Peabody mine broke during Friday night, and brought operations to a standstill at once, as the water rapidly rose and drove the miners out of the drift. This is an annoying accident to the company, as they had just commenced taking out ore of an excellent quality. This break-down will cause the shaft to fill with water, and another pump will have to be put in to drain the mine as the other pump in the meantime will be submerged.

MINING NOTES.—Grass Valley Union, May 25: The work of driving the tunnel in the Pittsburgh to a connection with the main working incline is progressing favorably, and it is expected that it will be completed in about one month, when the mine will soon be drained of water and regular mining operations started up. The shaft of the Grass Valley Company's mine (the Bobby Smith ground) on New York Hill, is now down 80 feet, and the work is being prosecuted regularly. The mine is well located and has heretofore prospected well, and there is every indication that it will prove an excellent mine.

Sierra.

GOLD KING QUARTZ MINE.—Sierra Tribune, May 24: Two men have been engaged in running ahead the new working adit at the Gold King Quartz mine, near Alleghany, this winter. There are yet 400 ft of tunnel to run before tapping the ledge. As the rock is very hard it is barely possible that the work can be accomplished before another season. It was reported that a Burleigh drill would be put in at the mine, but this is only a rumor and it is questionable whether it will be done or not. With the short distance of tunnel to be run it can probably be carried through in the ordinary way at a less expense and will require but little more time. Mr. Weldon, who has passed the winter at his home in Oakland, will arrive at the mine about June 1st. Before that date he will ship several months' supplies from below. Mr. Weldon is a live and energetic gentleman, and we are glad that he has been fortunate enough to find a lead that will warrant his remaining with us.

IN TOWN.—Supt. Lawrence, of the Brandy City mine, was in town this week and dropped in for a few moments' chat with us. He was down below not long ago and told those slickens fellows some pretty plain truths. However, they were unyielding so far as allowing his company to continue work at the mine is concerned, and so operations have been suspended there. The closing down of this claim is a severe blow to Brandy City, the effects of which we discuss more at length in another column.

PUSHING WORK.—B. F. Littlejohn, W. H. Graham and Mr. Lynch were down from the San Salvador gravel claim last week. This mine is located at the head of Nebraska, and a tunnel has already been run into the hill 145 ft. Y. C. Lawson, another one of the stockholders, is expected up from San Francisco this summer. The latter gentleman is in the employ of Wells, Fargo Express Co. at the bay. We are pleased to learn that he has recently been promoted.

BALD MOUNTAIN.—Mountain Messenger, May 24: The Bald Mt. Co., have raised ten and a half ft from the tunnel run from Lowell Avenue into the South Fork, and found fine looking gravel. There has been no clean up as yet, but two pieces of gold, worth \$3 each, were discovered in the riffles of the prospecting dump, Tuesday. The Bald Mt. Co., are steadily working back with their pillars, where the gravel pays well. About fifty men are employed. The main tunnel of the Bald Mt. Extension Co., is now in over a mile—3,500 feet in an air-line to the bend up the ridge. Breasting in No. 6 down stream, lately stopped by water and a cave, was resumed Monday.

ALLEGHANY.—All the drifting and placer claims hereabouts are yielding good returns, with a fair prospect of doing better in time. Ten men are employed in the digging at Smith's Flat, reported as yielding profitably. Last month 184 ft was made running the main tunnel of the Rainbow. Work was stopped for necessary repairs two and a half days last week. The new bridge across the creek is completed. Two Ingersoll drills, worked by compressed air, are managed by four men at the face of the main tunnel; and forty pounds of Giant powder used in a blast, two being put in each twenty-four hours; arrangements will soon be made for three. Main tunnel now in slate—air-line from mouth, 1,100 feet. About 1,300 more to run to reach the ledge. The ore when abandoned on account of water in the pay chimney above assayed \$100 per ton. Fully \$250,000 have been thus far expended in the development of this valuable property, and \$350,000 worth of rich quartz extracted. The new main tunnel will cost about \$60,000. The blacksmith shop at the mouth of the tunnel has been tumbled over by the force of the underground explosions. A large amount of supplies are now on the way to the mine from the lower country. Wm. Hanley, Jr. is Supt., and ably performs the important duties entrusted to him, and most courteously entertains visitors. J. O. Briggs, cousin of your President of the Bald Mt. Extension Co., is blacksmith. The prospect is good for the completion of the tunnel to the ledge so as to start the mill by next winter. The estimated value of the rich quartz chimney beyond is figured at least to be one million dollars.

C. S. Benham is in Sonora, New Mexico. It is reported that he will be here soon, and the Golden Gate quartz mine re-opened this summer, by running a tunnel 1,400 ft in from Wet Ravine to reach the ledge 600 ft below the old works, when it is believed that the mine can be made to pay. Nothing is being done at the Kenton ledge. The Spoon quartz mine is located midway between the Rainbow and Kenton on the south bank of Kanaka creek. The upper tunnel, now in 200 ft, is being run for the ledge. Two lower tunnels are in for the same distance,

The second will be extended with the third or highest, and then the two will be connected by a shaft for air. The property is owned by J. T. Bradbury, of Alleghany, who, with his sons and one hired man, is developing the mine. Ore prospects well with a hand mortar. A cannon-ball mill could be profitably used. The mine is reached by a trail from Alleghany. J. Booth and Wm. Wright have their tunnel, one mile and a half northeast of Alleghany, in 200 ft with fair prospect of soon reaching good pay. Several rich specimens have been found. The gold is of the same quality as that of the Bald Mt. Extension, and evidently from an outbreak of the main channel beyond the lava flow. The Mammoth Springs Co. are extending an old tunnel, run in early times, to find an extension of the rich lead that paid so well years ago. The Buckeye drift claim, one-quarter of a mile below Alleghany, Smith's Flat, is owned by B. Hockleberg, J. L. Patton, F. Barnhardt and A. Burgan. The main tunnel is in 1,700 ft. The gravel is soft and of a blue color. One breast is being worked by five white men—Thomas Murta, Jack Young, Dick Bennett, John Smith, J. L. McCormick. Two Celestials run the buggies from the breast to the chute. The pay is very good. This is reckoned as valuable mining property.

San Bernardino.

CALICO DISTRICT.—Calico Print, May 24: At no time since the first discovery of silver in our hills has the camp appeared as lively as at the present time. All the principal mines are looking well and working their full complement of men, while the chloriding element is doing a wonderful work in the development of property that a year ago was considered comparatively worthless. By slow degrees our prospectors are beginning to realize that no particular seam, reef, or variety of porphyry, carries ore to the exclusion of the others; but that every square yard of ground within the mineral belt must be inspected before an intelligent conclusion can be found as to the probability of its containing ore. This, together with the fact that some of the most promising ground in the camp has recently been thrown to individual enterprise, has given chloriding an impetus it never before has known. Scores of men are now at work on leased ground in various parts of the camp, and the majority are doing well.

SAM HOUSTON NO. 3.—Mr. R. B. Johnson, who so successfully operated this mine a year since, and then sold the property, has obtained a lease on the Sam Houston No. 3, Blackfoot and Santa Maria mines, and arrived on the 5th to commence operations. He struck a large body of ore immediately, and informs us that he could already furnish 100 tons as rapidly as it can conveniently be disposed of. Three men are now at work and more will be added as the work progresses. The ore is not as rich as the mine has produced, but we are assured that a \$100 grade can easily be made, and plenty of it.

BISMARCK.—This mine is still looking well and now that the tunnel from the south slope of the hill to the old works is completed, operations will be greatly facilitated. The position of the ore in the mine renders it necessary to remove a great quantity of waste rock, the disposition of which had somewhat perplexed the managers until the new outlet was decided upon.

PINTO.—Mr. Henry Myres, after almost a year spent in prospecting this mine, has been rewarded at last by striking a large body of high grade ore near the south line. In general character the ore is peculiar to the ore in the immediate vicinity, consisting of red chloride of silver, of the softest variety of porphyry. About 15 tons have been taken out and a great deal more is still in sight.

OCCIDENTAL.—The Occidentals Nos. 1 and 2, which were recently purchased by Mr. Wm. Raymond from the Oriental Company, are being worked by chlorides with good results, as are also the Thunder, St. George and others.

INVINCIBLE.—Work is still progressing on this mine. Mr. Thos. Allen has for the past six months been working the mine in behalf of the owners and has never failed to make it pay.

HUMBUG.—No ore is now being taken out, but three men are busily employed assorting the huge ore dumps—putting the first class in sacks, piling up the second and removing the waste.

KING MINE.—The work on the King mine is being driven steadily forward. The mine never looked better than it does at present. The ledge holds its own as to quality and quantity of ore.

LITTLE V.—In January last Mr. E. Woolman purchased a one-third interest in this mine, formerly owned by J. H. Kane. Pleased with his investment he soon afterwards bought another one-third interest of Wm. Raymond. Since first coming into the mine Mr. Woolman has been steadily employed in taking out ore, seven tons of which, averaging \$150 per ton, have been milled, and over eight tons now on the dump, are expected to yield \$200 per ton.

COMET.—Four men are now at work on this mine. A tunnel is being driven to crosscut the main ledge and two men are engaged in taking out ore.

SNOW BIRD.—Seven men are now employed in taking out ore on this mine. Seventy-five tons are waiting to be crushed at Mr. Sinclair's mill, which commenced its first regular run on Monday last.

A NEW DISTRICT FORMED.—Messrs. Kincaid, Eckles and Gray, returned on Friday of last week from the De Soto mine in the newly formed district of the same name. The new district embraces the west half of the old Lava Beds district. They report everything as encouraging, both there and at the Lava Beds. Thirteen men are employed on the Meteor mine, two on the Morning Star and several on various other claims in the latter district. Having accomplished the work they proposed to do on the De Soto, which was to procure a working test of the ore, they gave a contract for a 50 foot tunnel to be driven on the main ledge near the northwest end of the mine, and returned to look after their interests in Calico, and spend the hot season in more comfortable quarters. The work of development will probably continue throughout the summer.

Mr. Remi Olivier, who is interested in the De Soto mine, says his property is in first-class shape. They are now assorting their ore previous to sampling and as soon as returns are made will make figures public. Mr. George Dessalier, foreman of the Cuba, reports work on the Landers and Stewart McVey struck it on Tuesday. They have been working a claim across Wall street, and had done the assessment work on the same. While walking

around at some distance from their work they came on to croppings of a ledge from 15 to 20 ft in width. They took a few pieces to an assayer and got the following in silver: \$26, \$34 and \$64 per ton. Wm. Hale & Co., who have leased ground from Mr. Wm. Raymond, on the Garfield property, are doing well. The first day's work on the lease brought out 15 sacks of \$500 ore. The Thunder, located in East Calico, has taken out in three days' work nine sacks of ore, which was assorted and ran on an average \$2,000 per ton. The prospects are better than ever. J. W. Hudson, of Los Angeles, the owner of the New York mine, lately arrived in Calico to look after the development of his property. He has a few men at work engaged in cross-cutting from the shaft. Mr. Wm. Raymond is starting a tunnel to tap the mountain as low as possible. It will be 150 ft to the south of and 115 ft below the level of the present tunnel on the Garfield. The Kearsage is now down 80 ft in good ore, some of which is looking better. Mr. Stevens is drifting on both upper and lower levels. The St. George mine in East Calico, run by Whitfield, Hale & Co. on a six months' lease is doing well.

Shasta.

LOWER SPRINGS.—Shasta Courier, May 24: Jones & Son, of Lower springs are industriously at work putting up the works for their new quartz mill. The machinery will be run by steam power, and as the elder Jones is an engineer, he can attend to that part of the business. The mill separator, etc., will be put in running trim by a machinist from the San Francisco factory. There is now on the dump of the mine twenty tons of ore which assays well, and on White's claim near by there is a large amount of ore out ready for crushing. The prospects are now favorable for the development of the great quartz interests of the Lower Springs district. The mines there are undoubtedly rich and permanent, but have long suffered from the effects of getting a "black eye," from former attempts at working them by inexperienced miners and millmen.

MAD OX.—Cor. Shasta Democrat, May 24: The Mad Ox mine has proved itself to be one of the finest in Northern California. After running a tunnel of over 700 ft in length, they revealed a beautiful vein of good-paying ore over 600 ft from the surface. The Mad Ox mill is in constant motion, crushing from sixteen to eighteen tons per day. J. S. Strode has erected a cannon-ball mill on his mine. It works like a charm. It is reported that the Banghart mine will be worked next month. Jno. Daugherty is working a seam mine on Knobloch. He reports prospects very favorable. R. M. Manigal is seeking the hidden treasure in the Mad Mule mine. Owing to the insolvent condition of the Phoenix Company, their mill and mine still remains in the "pit." R. Warfield & Co. are working their claim on Mad Mule mountain.

Siakiyou.

ON THE KLAMATH.—Yreka Journal, May 24: Messrs. Brown, Bailey & Bowles, of the Grizzly Gulch quartz mine, Indian creek, crushed eighteen tons of quartz lately, which yielded about \$800, and now they intend sinking down on the ledge. Work is progressing steadily in the Empire quartz mine at Klamath river, in running the lower level, where the rock is very hard. Pieces of quartz are found, indicating probability of soon reaching the main ledge, towards effecting drainage of the shaft sunk down from the upper level on the ledge, where it was impossible to work on account of too much water. The Highland Chief quartz claim, owned by Messrs. Jacobs, Renner & Co., on Klamath river, below Capt. Pope's ranch, is now being gradually prospected, and it is the intention to soon put up an arrastra which can be run by a wheel set in the river. The Fort Jones Company at Klamath river expect to have their wing-dam completed in about a week or ten days, and will then start their pump and hoist gravel also from the top bench. We learn from Dick Smith, Captain of the Lime Gulch claim, Klamath river, that work is progressing gradually in preparing for summer work, and that the boys will be ready to commence hoisting next week.

Trinity.

QUARTZ ON NEW RIVER.—Trinity Journal, May 24: Miner writes from New river, under date of May 11th, as follows: "The quartz excitement here, at the present time, is raging furiously, on account of the recent rich strike made by Ladd & Clemens on the Hard Tack ledge. It is, indeed, a big thing. With a hand mortar and a spring-pole attachment they pounded eight flour-sacks of rock and got \$299. The ledge measures sixteen inches at the bottom of the shaft, 14 ft from the surface. Last week they refused \$10,000 for the ledge. All other parties owning ledges here are in readiness to commence operations, and we predict something handsome will be realized from quartz in this section during the summer."

NEVADA.

Washoe District.

YELLOW JACKET.—Enterprise, May 24: The old upper levels continue to yield well in the usual character of ore, keeping the river mills at work. The prospecting operations disclose low-grade ore at several points. While the miners are engaged in extracting the bodies of ore brought to light by the exploring drifts, the prospectors push ahead in search of new deposits. In this way a considerable amount of ore is kept opened up in advance.

HALE AND NORCROSS.—Work has not yet been resumed on the 280 level, where rich ore was found in drifting north. Over 800 tons of ore have been extracted from the newly-discovered deposit on the 200 level. This is taken out through the F street tunnel and placed in the ore dumps near the railroad track ready for shipment to the mills.

BEST AND BELCHER.—The north drift on the 2700 level has reached ground containing a great deal of hot water, and progress is slow. It will probably be necessary to discontinue work at that point for a time, until the hot water drains out, as it heats the drift to such a degree that the temperature is almost unendurable.

GOULD AND CURRY.—Are waiting for the water to drain out of the southeast drift on the 2700 level. The water is decreasing, but it still makes the drift very hot. On the 1200 level two crosscuts have been started east and are passing into favorable formation containing frequent streaks of quartz and seams of clay.

CON. VIRGINIA.—The east drift on the 2900 has

been extended about 30 ft. Are still repairing the U. and C. joint shaft. The material encountered in the drift is the usual vein porphyry. It presents a favorable appearance, being of an open character, with seams of clay and stringers of quartz.

UNION CON.—West crosscut No. 4, recently started, is out about 20 ft. The material is vein porphyry, with a good deal of quartz and clay in seams and streaks. The diamond drill is being run from the face of west crosscut No. 1. As yet it shows but little water.

ALTA.—Drifting west along the diamond drill hole, on the 2150 level. The diamond drill has been set up at the face of the east drift on the 2150 level, and is ready to be started up as soon as the diamonds for the drill are received from New York.

MEXICAN.—The winze on the 3100 level is down about 72 ft. The bottom is in the selvage material lying on the east side of the ore vein. There is a little water in the bottom, but in the last day or two it has not increased in volume.

SIERRA NEVADA.—The northeast drift on the 3100 level has been turned and is now going nearly north. It is in a species of birdseye porphyry, the ground of which is nearly white. The ground is perfectly dry. No other work is at present doing in the mine.

IMPERIAL. The lateral drift is in Alpha ground. It has encountered a great deal of quartz, but this has as yet yielded no assay of much value. The drift has encountered much hard rock during the latter part of its progress.

CROWN POINT.—The usual amount of ore is being extracted, and the mills on the Carson river are kept running to their full capacity. The prospecting drifts are showing a considerable amount of ore at several points.

BELCHER. All work in the old upper levels is going on about as usual. Ore enough being extracted to keep the mills in operation. A considerable amount of work in the way of exploring and prospecting is being done.

CALIFORNIA.—The usual progress is making in the east drift on the 2900 level. The repairs to the C. and C. joint shaft are still continued. The ground passed through continues of a favorable character.

OPHIR.—Are still finding some low grade ore in the filling of the old drifts and other opening on the 250 level. The ore extracted is being worked at the Morgan mill on the Carson river.

UTAH.—During the past week the south drift on the 1950 level has been advanced 30 ft. It is still in vein porphyry with some clay seams and occasional streaks of quartz.

ANDES.—Some low grade ore is being extracted and a good deal of work is being done in the way of exploring and prospecting.

UNION SHAFT.—Are repairing the drain drift on the 1600 level. This drift leads out to the north branch of the Suro tunnel.

SAVAGE.—Good progress is making in the construction of the stone bulkhead in the north drift on the 2600 level.

SCORPIO.—The west drift in the 500 level is still in vein material of a favorable character.

CHOLLAR.—Are preparing to place a stone bulkhead in the drift on the 2600 level.

Columbus District.

MOUNT DIABLO.—*True Fissure*, May 24: During the week the east drift from the north crosscut on the third level, east of the shaft, has been advanced 10 ft, and shows a small streak of good ore. Winze No. 6 is down 93 ft, and there is some low grade ore in the bottom. The west intermediate, between the second and third levels, has been driven 11 ft and shows a small ledge of \$40 ore. In the east intermediate, between the same levels, the north crosscut has been driven 6 ft and the west drift 9 ft. The south crosscut from the east drift on the second level has been advanced 18 ft; total length, 230 ft. The north crosscut from the same drift is in 108 ft. The west drift on the second level shows a small streak of \$80 ore. The raise from the east drift on the first level shows a small amount of \$90 ore. The incline has been sunk 12 ft during the week and is now 143 ft below the third level. Rollers for the rope have been put in from the third level to the shaft and a sheave is being put in the shaft.

COLUMBUS CON.—Operations are still confined to the 150 foot and second levels. Crosscut No. 3 from the main drift on the 150-foot level was extended 5 ft and is now about 43 ft in length. The ground is hard, but is breaking a little more easily. The upraise on the streak of ore encountered in the south crosscut from the same level is now up a distance of 18 ft, and is about 18 ft in width at the top. The width of the ore vein is 2 ft, and the assays average \$60 per ton. The work in the other parts of the mine is confined to getting matters in readiness for future prospecting. But little is being done other than on the levels mentioned.

SILVER BOY.—The appearance of this prospect, which is becoming a mine, improves as the development progresses. The winze from the tunnel level has reached a depth of 30 ft, at which point a drift has been run to the east about 10 ft and is still in ore. A crosscut will soon be started to determine the width of the ledge at the depth attained in the winze. A station has been cut out from about the mouth of the winze and the tunnel extended beyond it 10 ft. From this point a drift has been run to the west a distance of 20 ft, and has encountered a body of good ore.

Eureka District.

NOT SO DULL AS IT SEEMS.—*Sentinel*, May 25: There are fewer men on our streets now than for a long time past. This gives the town an air of greater dullness than is justified by the facts. Many of the men who, a while ago, could be seen about the streets and in the saloons, have taken to the hills and are vigorously at work prospecting for ore, or taking it out and shipping it to the furnaces for reduction. On Prospect mountain, for instance, more miners are agitating earth's bowels than ever before, we believe, in the history of the camp; and the most of them, as we have reported from time to time, are making wages, and some of them, also, getting handsome returns for their labor. Adams Hill is fairly alive with miners, whose number is increasing from day to day, and there is not one of them but is making good wages. A little while ago, for example, the Silver Lick mine was lying idle; now 18 men are tributing in it, several of whom

have fine pitches. It is no bad sign that the number of idle men about town is reduced. They are at work keeping the furnaces alive for the present, and the chances are that among so many prospectors a big mine will be uncovered before winter comes again.

Florence District.

RATTLESNAKE.—*Cor. Virginia Enterprise*, May 25: Rattlesnake, in Florence district, promises to soon loom into prominence. The Louisa, Oliver Twist, Sedan and other claims have fine showings of free-milling ore. Messrs. Streitberger, Bohle, Meyers et al, are the fortunate owners.

Garfield District.

THE NEW FARRINGTON MILL.—*Candelaria True Fissure*, May 24: Archie Farrington is now busy with the erection of a five-stamp mill at a spring on the ground known as the Horse Ranch, about eight miles northwest of Soda Springs. He intends reducing in this mill the ores from his mines in Garfield district, which lies but a few miles northeast. When this is in operation and the smelter at Soda Springs is again started, there cannot be any doubt that there will be a perceptible stir about the station.

Jefferson District.

CHLORIDE ORES.—*Cor. Virginia Enterprise*, May 25: Jefferson, having suffered so fearfully in the endeavors to recover from the blows given it, will employ a few men in the Keystone, St. Charles, Silver Point, Silver Vein, Jefferson, Carbonate and Woodbridge claims. County Recorder Delano, J. Heydon, G. Cook and A. Delano have taken out some very rich chloride ore, carrying free gold visible to the naked eye, from the Woodbridge. This will be worked in the arastra belonging to the Harrison Brothers. W. Garrard, K. Robinson and J. Wilson, having a fair ledge in sight, will work the Keystone mine. Charles Kanrohat is leaching out the ore from his Jefferson Carbonate claim in diminutive home-made leaching works. F. Carrios and J. Enghouse will prospect their properties known as the Silver Vein and Silver Point mines respectively. The Harrison Brothers will work the St. Charles.

Osceola District.

PLACERS.—*Ward Reflex*, May 18: A large number of men are going into Osceola for the purpose of putting in their biggest licks at placer mining while the water lasts, so we are informed by James Matson, who came over from that auriferous region Sunday last. L. Leavitt writes from Osceola to Poujade & Garaghan, who are interested with him, that he commenced sluicing Monday with 100 inches of water, expects much more and has eight men, four on a shift working night and day. He says there are 50 men engaged in placer mining in the district. L. Leavitt left for Osceola Saturday, for the purpose of working his placer claim. The claim he purposes working adjoins the one on which the "Darling" nugget was found in 1877, and which was valued at about \$4,250. It was named after Darling, who was employed on the claim, who found it and attempted to get away with it. He finally "whacked up" with the owners of the claim who got \$2,640 out of it. Such a nugget found in the Cœur d'Alene would set the country wild, but find it in Osceola and it is not worth noticing. Competent judges do not hesitate to say that this isolate placer cannot be worked out in ten years with all the water that can be brought to bear upon it. All it lacks is water. The water is in the neighborhood, but men of means cannot be induced to bring it in.

Reveille District.

LEACHING.—*Cor. Virginia Enterprise*, May 25: Reveille has recently been blessed with a new acquisition. Charles A. Ogden has completed the erection of small but adequate leaching works for parties there. It is believed that the works will be supplied with ore taken from the once famous Gila mine, owned by Governor Adams.

Taylor District.

MONITOR.—*Ward Reflex*, May 18: The Monitor Mining Co. shipped three bars of bullion Tuesday, valued at \$4,993 98. This is the first shipment since the mill started up. When the Argus mill gets to "cross lifting" with the Monitor, a considerable stream of bullion will go out of Taylor district. We hear that another and richer strike has been made in the north end of the Argus Co.'s mine in Taylor district.

Tuscarora District.

A SPLENDID PROSPECT.—*Times-Review*, May 21: The Found Treasure claim near the Commonwealth, has by far the best surface prospect that was ever discovered in the district. At a depth of 18 ft there is a ledge four ft in width, nearly all pay ore, which experienced miners estimate will average \$300 per ton. There is a vein of about eight inches which will probably work upwards of a thousand dollars. The ore is mostly a gray chloride, although near the bottom of the incline on the foot wall there is a streak of rich sulphurets coming in, which is gradually widening and which will probably, when sufficient depth is attained, fill the entire space between the walls. On the surface the ledge was twisted and broken, although interspersed with small veins of rich ore, but upon sinking a few ft it became solid and uniform, with well defined walls which have continued unbroken and of a regular pitch of about 45 degrees as far as the incline has been sunk. It has every appearance of a true fissure vein, and miners who have examined it are unanimous in the declaration that it surpasses anything, so far as prospected, that was ever struck in Tuscarora. The location is owned by Mrs. Eliza Graham. A short time ago she leased it for six months to Joseph McGowan who has made the recent developments, and the probabilities are that the lessee as well as the owner will realize handsomely out of the property.

THE MAYFLOWER PROSPECT.—*Times-Review*: The owners of the Mayflower location are sinking an incline on their ledge about 200 ft southeast of the Found Treasure workings. They are down about 12 ft and have a strong ledge with a small vein of rich chloride ore which is however gradually widening and which they believe will develop into a body of sufficient dimensions to be profitably worked. The ore is the same as that in the Found Treasure, and it is undoubtedly the same ledge. The locators are determined to thoroughly prospect their claim, and are confident that they will be well paid for their labor in the end.

Tyler District.

WILL START UP.—*Cor. Virginia Enterprise*,

May 25: Tybo, though comparatively inactive, will start up on 2 G carbonate and galena ore on the return of Supt. N. S. Frowbridge. Lively times may then be expected, as the mine never looked better.

Ward District.

MARTIN WHITE.—*Ward Reflex*, May 18: We have heard no report here that the Martin White mine will close on account of a suit by Martin White against the company. As we understand it, the judgment is against individual members of the Board, and that it in no way affects the mine. The contract made with Martin White, which he claims was "breached," was not an official act of the Board.

Willow Creek District.

FINE PROSPECTS.—*Silver State*, May 24: Thomas Edwards returned yesterday from a visit to the Willow Creek mines. He reports considerable activity in the camp, and the prospects bright. An Arizona expert is now in the district in the interest of a New York company, and he will remain a week or more looking at the mines. Judge Harlan has a force of men taking out ore in the Golden Era mine, and, as soon as the road which is being built to the mine is completed, he will start the mill. Andy Shrewsbury is at work on a gold-bearing ledge which is supposed to be the same as the Penobscot Boy. It is about thirty ft wide, and rich in gold. The Penobscot Boy, owned by McPhetres & Co., is sixty or seventy ft wide, with gold in paying quantities all through the ore. Supt. Mayon was waiting for tools and supplies to commence work on the Pauline, one of the Eureka Company's mines. He intends to start in on the lead, which crops out low down in a ravine, and follow it into the hill. Yesterday Elias Jones' team left here with tools and other articles for the Pauline, and work will probably be commenced on the lead next Monday. Mr. L. Edwards says the surface prospects indicate large and rich leads, but, as yet, none of them have been opened to any great depth. The gold-bearing leads are generally very large, and, besides these, there are promising silver mines in the district, among them the Ohio, which has produced considerable ore.

COLORADO.

THE MINES AT EMPIRE.—*Cor. Colorado Miner*, May 24: The Bay State mill started up on Wednesday, and bids fair to give the miner pay for his labor while developing his property. Young and Thomas are getting out fine milling ore from the Great Equator, on Silver mountain. The Ingersoll, on Covode mountain, has a one hundred foot shaft, with a fourteen foot drift near the bottom where the crevice is three ft wide, bearing iron, galena and carbonate of copper. Assays from this lode have run from 107 to 149 ounces silver, and from 1 to 2½ ounces in gold per ton. Mill runs from this property have averaged \$51 per ton. The Rara Avis, owned by Monck & Baker, has a shaft 45 ft in depth on a crevice about ten ft wide, discovered little more than a year ago. A rich flow of silver glance had been found from time to time in the vicinity of this property, but until February, 1883, was never found in place. Assays from the Rara Avis at four or five ft deep have given as high as 369 ounces silver per ton. An extension, west, called Bonanza, owned by Smith and Baird, promises well, specimens from which, assayed for gold and silver, gave 6 to 10 ozs. gold and 151 ounces silver per ton. There is only about forty ft of development on this property. The Windsor, now being worked by Husted & Co., is improving fast as depth is gained. The upper drift is ninety ft in length, forty-five ft below which is another one hundred ft in length, where they are now working. The crevice at the breast is four ft wide, with a pay streak one foot wide, of iron bearing galena and yellow copper.

DUMONT MINES.—An inferior pump at the Albro mine has impeded the working of the shaft for some days. Another pump has been substituted. One carload of smelting ore was shipped to Denver this week. Al. Penery, lessee on the Standard lode, informs our reporter that he now has stuff that will run sixty ounces gold to the ton. He seemed somewhat reticent, so our reporter turned away a weary gleaner. Will interview him when he has a run. The last mill-run from the Lee gave the following: 3 3-ro ounces gold, 12 ounces silver, and 2 per cent copper to the ton. A mill-run from the Syndicate mine last week gave the following: 152 ounces silver and 99 ounces silver to the ton, according to class. Good Luck, owned by Baumgarten & Freidlander, adit on line, forty ft. A shaft has been sunk to a depth of fifty ft at the breast of the adit, the bottom showing both walls. The hanging wall carries a ten-inch vein of nearly solid ore. The foot wall carries a four-inch vein of solid ore, the character of which is galena, iron pyrites and psilomelane.

GRAND COUNTY MINES.—*Prospector*, May 22: Work has been commenced on Willow creek and the probabilities are that something will be developed. Messrs. Westcott and Miner, who have just returned, bring some very fine specimens of placer gold. They are extremely sanguine, and will return as soon as they can procure lumber to make sluice boxes, etc. Mr. Frank Miner informs us that he can make good wages with a rocker. Parties at Empire have been making negotiations with Lehman, Spurgeon and Arnold for 100,000 ft of lumber to be delivered on Willow creek, to be used in the construction of sluice boxes, flumes, etc. Caswell, Pollard & Co. will begin work on their placers as soon as the snow goes off.

IDAHO.

THE MINERVA.—*Ketchum Keystone*, May 20: The strike made on the dividing range between the Elkhorn and the North Star mines by Hillebrand and Donski, has been named the Minerva, and proves to be one of the finest leads in the section. The ledge, fully developed, is ten ft wide and carries a fine ten-inch vein of solid galena. Float was found on a claim located below the Minerva for working facilities and yesterday, after two days' work, a second ledge was discovered carrying green, blue and dark sulphurets, very heavy, and possessing every indication of excellent the former. This claim has been named the Triumph. The Minerva is very probably a continuation of the North Star mine. It has been traced and uncovered at distances of 500 ft. Messrs. Donski and Hillebrand, the lucky owners, were in Ketchum to-day laying in supplies. They

have several more prospects in the East Fork region, but will not forget to develop the Minerva and Triumph lodes as these surpass anything else they have discovered.

A NEW DISCOVERY. *Ketchum Keystone*, May 24: Messrs. Connors and Spainhour came in from the Elkhorn vicinity with the good news of another strike. They were prospecting the hill opposite the Parker, north, and struck a blind ledge under the surface when it cropped out with good walls about three and a half ft apart. The vein is about 10 inches containing some fine ore.

MONTANA.

CLEAR UP.—*New Northwest*, May 29: The Kelley Hagan & Co., mine, on Pioneer Gulch cleaned up last week \$2,568.75, the first of the season, this being the result of the work of two Little Giants on the upper line of the claim. Last Monday a complete rig of two more Giants were started up near the center of the ground, which promise fully as good results. With the most complete appliances for Placer mining, including four Giants, constantly at work, it will take from twelve to fifteen years to work out this one claim.

THE MOULTON DIVIDEND.—*Inter-Mountain*: The payment of a \$20,000 dividend by the Moulton Mining company is a matter for congratulation. It is an honest dividend, honestly earned from the operation of a meritorious mine. The Moulton is not a high grade property, but it has been skillfully and economically developed. Not long ago it was heavily in debt, almost as much so as the Alice, but when it once was put on a paying basis its earnings were applied to the liquidation of the debt and no dividend was thought of until the encumbrance was cleared. The dividend has not been paid in order to enable money lenders to continue drawing interest on the company's notes and overdraft, but because the mine is on a paying basis, because there is in sight in the mine enough ore to insure continuous profits, and because Mr. W. A. Clark recognizes the rights of stockholders to a share in the profits of the mine. The Moulton will hereafter be a dividend paying mine, and it will be worked in Butte not in New York.

PHILLIPSBURG.—The San Francisco is a mineral deposit, now securely entrenched between two perfect quartz walls, shows decided improvement with every foot of development gained. The granite horse, (previously noted) has been completely cut out and the header shows three feet of solid ore with clay casings on both walls. The entire length of ore shute presented by the tunnel to date is 109 ft, and the assay throughout shows the rock to be of a profitable milling character. Noticing John Ullery digging in the waste dump yesterday, upon inquiry, I ascertained that at least 100 tons of good rock had been carelessly covered up during the past winter.

WINGER. No. 2.—McDonald & Company have struck high grade rock in the 50 ft cross-cut of this mine and have about 75 tons of ore on the dump. There is no incentive to cause the owners of the Winger to hoist pay ore, as it is impossible to get it worked in the camp, and it must be shipped to either Butte or Anaconda to be made productive this summer.

NEW MEXICO.

CHLORIDE CHRONICLES.—*Black Range*, May 24: Messrs. Caldwell and Gillem are doing assessment work for 1884 on the Mountain King mine, on upper Chloride creek. Three men are stopping ore from the Colossal. Nobody cares to take a new contract on the shaft without machinery to keep down the water. Charley Ridgely and Bob Norton are sinking twelve ft in the last shaft sunk on the Midnight, on contract. This will make the upper shaft 22 ft deep. Every foot gained in depth improves the quantity and quality of the ore, and increases the value of the property. On the dump of the King No. 2 mine there are several tons of shipping ore. When the wagon-road up Iyer's run, which M. H. Chamberlin and Fred Stevens are now at work upon is completed, this rich ore will be brought down and sold to Mr. Castle for shipment. The short season of work of the Silver Monument mine and the two weeks' work of the concentrator have already made a noable improvement in the finances of this camp. A few weeks more of the same will put Chloride on a high wave of prosperity.

THE REDUCTION SITE.—*Silver City Enterprise*: After ten days' delay the site for the new concentrating and reduction works has been secured, and the work of construction is being rapidly pushed forward. The promoters were disappointed in not obtaining the site promised them by a representative of the railroad company, but are satisfied in securing the next eligible location. Arrangements have been made with John Brock for the site below the Carrollton mill, and the property has been purchased for a nominal sum. It is convenient and suitable for the works, a sufficient supply of water for all necessary purposes being easily obtained. The machinery from Oak Grove has arrived and is being erected. The True vanners and Rapid ore concentrators will be ordered immediately and Mr. Norton informs us that the works will be rapidly constructed, and that, too, without further delay. The shaft of the Nugget mine, on which the Williams boys are working, has attained a depth of 140 ft, and it is estimated that 60 ft more will reach the ore body. A new whim has been ordered and will be erected as soon as it arrives. The shaft is being sunk at the rate of two and a half ft per day. Five tons of concentrates from the Cooney mine arrived in town from Alma, Monday. The regularity with which concentrates arrive from this excellent property is a better card for the camp than all the "blowing up" it could have through the papers. The Cooney mine is a success. Messrs. Frost, Waller and McDonald made another shipment of four carloads of ore from the Two lkes mine, in Chloride flat, on Tuesday. The ore is about the same grade as the thirty-six tons recently shipped from the same property by these gentlemen and which netted them 102 ounces per ton. Fifteen miners are employed upon this property and regular shipments of ore will continue until sampling and reduction works are erected here. Some very rich ore, containing native silver and argentine, has been struck in the Good Hope mine, at Bullard's Peak, owned by H. M. Carpenter, and upon which work is now progressing steadily.

PATTEN'S
CONCENTRATOR AND AMALGAMATOR COMBINED.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in a very short time. One machine will concentrate the tailings from a five-stamp battery.

The undersigned is now located at the Elina Iron Works, 217 to 221 Fremont street, where he is building the above machines and prepared to fill orders, and guarantee them to do all that is claimed. Estimates given and orders promptly filled for all kinds of mining machinery.

C. W. PATTEN, 217 Fremont Street, S. F.

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Holts for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

Among the late discoveries in the Economic Arts stands prominently that of Engraving by the Art of Photography. While the new methods and processes greatly lessen the cost of producing the special kinds of printing plates most suitably made by the aid of photography, one of the best results gained is the perfect accuracy that is obtained.

Improvements are being continually made through more experienced workmanship, and ingenious and wonderful inventions that are exceedingly interesting and useful.

Portraits of men and women are made remarkably perfect in likeness. The same of animals, plants, flowers, fruits, vegetables, landscapes, buildings, etc.

Nearly all kinds of engravings for books, pamphlets, trade catalogues, circulars, cards, handbills, labels, certificates, and other varieties of printing, are made with great advantage and desirability.

Some kinds of illustrations can still best be done on wood, and will long continue to be so made, for various reasons. It is our purpose to use the best available methods for accomplishing economically the most satisfactory results, and work is therefore solicited for all kinds of engraving.

All Publishers, Printers, Societies, Schools, Companies, Scientists, Professional Men, Merchants, Stock-raisers, Horticulturists, Mechanics, Manufacturers, Tradesmen, and all others requiring Engravings, should call and inquire, or write particularly for any further information desired, to the OFFICE OF THIS PAPER.

On inquiring prices, send samples of work similar to that desired, when practicable, or otherwise give as clear an idea as possible of just what is wanted.

⚡ Satisfaction guaranteed on all orders.

DEWEY & CO.'S

Scientific Press

Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

A. T. DEWEY.

W. E. EWER.

GEO. H. STRONO.

PACIFIC POWER CO.

Room with steam power to let in the Pacific Power Co.'s new brick building, Stevenson street, near Market. Elevator in building. Apply at the Company's office, 314 California street.

HENRY KIMBALL

BARTLING & KIMBALL,

BOOKBINDERS.

Paper Rulers & Blank Book Manufacturers
505 Clay Street, Southwest cor. Sansome,
SAN FRANCISCO.

Dewey & Co. { 252 Market St. } Patent Ag'ts.

Is the Best Pump in the World. Another New Improvement is Lewis' Patent Spray Attachment.

Can change from solid stream to spray instantly. Regular retail price \$6. Weight, 4 lbs. Length, 32 inches.

FOR SALE BY JOHN H. WHEELER,
111 Leidesdorff St., S. F.

P. S.—A sample can be seen at this office.

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

[From the official list of U. S. Patents in DEWEY & CO.'S SCIENTIFIC PRESS PATENT AGENCY, 252 Market St., S. F.]

FOR WEEK ENDING MAY 20, 1884.

298,812.—TOPOGRAPHICAL MODEL—C. L. Anderson, S. F.
298,835.—GAME COUNTER—Frank Dayton, Portland, Or.
298,734.—APPARATUS FOR REDUCING SULPHUR—F. Dickert, Salt Lake, U. T.
298,844.—BOTTOMS FOR BOOTS OR SHOES—C. F. Glanville, S. F.
299,068.—OIL CAN—J. A. Griswold, S. F.
298,746.—FIGURE AND CHART FOR EDUCATIONAL PURPOSES—Mary E. Guirey, S. F.
298,752.—NECKTIE FASTENER—P. H. Higgins, Merced, Cal.
299,084.—HOISTING APPARATUS—W. F. Murray, S. F.
298,888.—BORDER LIGHT FOR THEATRES—J. T. Preddy, Carson, Nev.
299,009.—CARTRIDGE LOADING APPARATUS—Quinan, Kimpfel & Olsen, S. F.
298,793.—TANK FOR WINDMILLS—H. R. Stevens, Los Angeles, Cal.
298,915.—OIL CUP—W. H. Thomas, Santa Ana, Cal.

NOTE.—Copies of U. S. and Foreign Patents furnished by Dewey & Co., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

CARTRIDGE LOADING APPARATUS.—Wm. R. Quinan and Frank Kimpfel, S. F., and Jacob Olsen, Marin Co. No. 299,009. Dated May 20, 1884. This is an apparatus for packing nitro-glycerine powders and other pulverulent substances into cartridges or tubular cases made of paper or other material. This packing is usually done by hand, one cartridge at a time. The object of the invention is to produce a machine which may be operated by hand or power in which a number of cartridges can be packed at one operation with the same safety as ordinary hand-work. The principle of the invention may be illustrated by an open-topped box, within which a system of parallel rods pass through two opposite sides near the bottom. The box is filled with powder and the rods being drawn back until their ends are well within the box and then pushed forward, each rod will carry a charge of powder through the opposite hole and into the cartridges, which are held on short tubes projecting outward from the holes. A succession of strokes fills the cartridges, packing each charge until the whole cartridge is filled and packed.

NAUTICAL PARALLEL RULER.—Chas. Hutchinson, S. F. No. 298,471. Dated May 13, 1884. This is a nautical instrument more particularly useful for shaping courses and taking cross bearings. It consists of parallel rulers upon which is pivoted a plate marked with the points of the compass, and adapted to turn thereon, and an arc or arcs adapted to indicate the angle or degree of variation to which the compass is turned. The object of the invention is to provide an instrument adapted for use in shaping courses and taking cross bearings, in the use of which there will be no liability of mistake, and which can be handled easily and rapidly.

MACHINE FOR CASTING LEADS ON FISH NET LINES.—Erick Manula, Astoria, Oregon. No. 295,262. Dated March 18, 1884. This invention relates to a new and useful machine for casting the leads or sinkers on the lines which go to form fish nets; and it consists in a peculiar reel or winch upon which the line is wound, and having its circumference constructed to form one-half the matrix in which the line lies, and a projecting arm under which the reel passes forming the other half. It consists, also, in the means for conducting the molten metal into the matrix and cutting it off, and the means for clamping the two parts together during the casting.

TWO WHEELED VEHICLE.—Wm. T. Goodman, Fulton, Sonoma Co., Cal. No. 296,949. Dated April 15, 1884. This is an invention for preventing the rocking motion imparted to these vehicles by the joggling of the horse. The improvements consist in the arrangement and connection of springs, the means for mounting the body thereon, and a novel connection between the springs, axle and shaft. In this cart the body may move readily independent of the springs to a certain degree. On account of the character of the springs themselves and the manner in which the body is hung, the vehicle is an easy riding one.

BOTTOM FOR BOOTS AND SHOES.—Conrad F. Glanville, S. F., assignor of one-half to Wm. H. Yeo. No. 298,844. Dated May 20, 1884. This improvement in making the bottoms of boots and shoes consists of a flange or rim of rubber interposed between the inner and outer soles, so as to form an in-

closed air space between the central portions of these soles within which is also placed a spring or springs. The rubber casing and spring make the boot more easy to the foot, and at the same time prevent the leather from cracking and strains on the stitches, and cause it to wear longer.

HOISTING APPARATUS.—Wm. F. Murray, San Francisco. No. 299,084. Dated May 20, 1884. This invention relates to a hoisting apparatus and a means by which the rope-winding drum is thrown into or out of contact or action with the driving gear; and it consists of a frictional device between the drum and gear, a stem or spiral extending into the hollow drum shaft, so as to act through appropriate connection upon the drum itself, and an eccentric or cam and gearing by which the stem may be caused to act or be relieved, and a means for compensating for wear of the frictional surfaces.

BUTTON.—Napoleon B. Hale, San Bernardino Co. No. 293,082. Dated May 6, 1884. This invention relates to a new and useful button of that class on which the stem or shank is provided with a sliding or swinging cross-head, whereby the button may be readily inserted and secured in place. The shank and cross-head are both made flat, and the latter of spring material. The object is to provide a button of simple construction, which may be easily inserted and fastened. The improvements are applicable to any and all kinds of buttons whether to be used for cuffs, collars or other garments.

HORSE COLLAR.—Charles Staufenheil, San Luis Obispo Co., No. 29,8126. Dated May 6, 1884. These improvements consist in making the collar in two equal parts, joining at the neck or throat; in a peculiar flexible joint at these points, and means for adjusting the joints to increase or diminish the size of the collar; the means for securing the joints; in peculiarly located seams to increase the space between the rim and belly for the better security of the harness, and in a peculiar lining to prevent displacement of the stuffing.

COLLAR.—Alexander J. McAdam and Neil L. McAdam, S. F. No. 298,489. Dated March 13, 1884. This invention relates to a new and unique improvement in shirt collars, the object of which is to prevent the cravat or necktie from getting out of position. The collar has two slots or openings in its back below the corner edge of the neck-band portion, one being on each side of the back button hole. The neck-band of the cravat is passed through the slot openings so the cravat cannot move upwards.

TRAVELING BAG.—Chas. A. Zinkand, San Francisco. No. 298,050. Dated May 6, 1884. The invention relates to the class of traveling-bags including valises, satchels, etc. in which the two sides open upon a longitudinal central, pivot line or hinge at the bottom. The invention consists, in connection with the bar which forms the hinge on the inside, of a bar connected with its ends and extending parallel with it, but on the outside, said bar forming a protection of the bag, and the two bars forming a fastening for the linings, the edges of which are inserted between them.

PATTON'S CONCENTRATOR.—Mr. P. Easton, of Sonoma, Tuolumne Co., writes to Mr. C. W. Patton as follows: "I can say of your concentrator that it is good for what it is recommended to do. It will save the sulphurets from a five-stamp battery well. I send you sample of the sulphurets as they come from the concentrator, and have two tons of this description. I fully endorse what Mr. J. H. Neal says about your machine. Every millman ought to have one."

LAP BOARD.—Adam L. Anthony, Placerville, El Dorado Co., Cal. No. 296,219. Dated April 22, 1884. The improvement consists in sliding sides or leaves and in hinged corners, whereby the lap board may be closed up to smaller dimensions, either for convenience in use or transportation. The object is to provide an extensible lap board which may be adjusted to different sizes and closed up for transportation.

LAMP BRACKETS.—Alfred Thurher, Concord, Contra Costa Co., Cal. No. 297,317. Dated April 22, 1884. This invention relates to a bracket or support for lamps; and it consists of an arm pivoted or suspended and having an automatic clamp at its outer end, the jaws of which are so constructed as to open and admit the shank or top of the lamp when it is presented, and close to hold it suspended.

SAW SWAGE.—Simon Kinney, S. F. No. 297,696. Dated April 29, 1884. This is a saw swage of that class in which, through compound levers, power is acquired to operate clamping devices to hold the sides of the tooth and pressure devices to swage it. The object of the invention is to provide a machine adapted to receive, clamp and swage a saw tooth to the best advantage and with small exercise of the original power.

LAND ROLLER.—Kinzy W. Jones, Lemoore, Tulare county, Cal. No. 298,475. Dated May 13, 1884. This is a roller for agricultural purposes. The main frame has two rollers, and is combined with a forward frame having one roller, by means of iron connecting arms, the method of construction being peculiar.

Brain Work Needed Everywhere.

An erroneous opinion has got abroad among mechanics that the wonderful progress which has been made in machinery of late years, has to a large extent, done away with the necessity which formerly existed, of a thorough manual training in the shop—such a training as was obtained through the old-time apprentice system. A similar idea has also been obtained in regard to the present need of brain-work in the shop. The fact is there never was a time in the history and progress of the mechanic arts when there was greater need of careful and trained manipulation, combined with the highest order of brain work than now. No machinery can be properly cared for and advantageously run without a previous thorough manual training. A person in charge of machinery should have a well trained "mechanical eye," the ability to see, as it were, "right through any intricacies that may be connected therewith, and a faculty for readily "fixing things" when anything gets out of fix, or goes wrong, as the very best of machinery will sometimes do.

Then again, to run machinery so as to keep it in order and do good work, the operator must have in addition to a knowledge of the working and construction of the instrument, some idea of the mechanical forces which are thereby called into exercise, he must have a thorough technical education to supplement his manual dexterity. This necessitates general education, thought, brain work. The statement is often made that good common sense is better than a college education. The underlying fact is that neither is of much account without the other. A collegiate education, to be really valuable should stand on a basis of good common sense or *vice versa*. One of the most difficult things to impress upon the mind of the average graduates of either the high school or the college, is the fact that all school education is but a foundation upon which to build the real practical education, by the use of which we must work our way through life. Our success in life will depend more upon the development of the latter than the former. When a young man has sense enough to appreciate this fact, and the application to use his opportunity to the best advantage, you may rely upon it that he will rise to something above mediocrity even in the most eminently practical community in the land.

There are but few so constituted by nature that they will make the necessary effort to rise as mechanics. The number is so few that with all the scramble and competition in our most crowded communities, there is an abundance of room for those who will make the proper effort—"there is always room at the top of the ladder."

The constant improvement in machinery and in the practical arts and sciences, and not less so in the learned professions, keeps up a constant demand on all the various resources of knowledge and thought. In the shop, on the farm, at the mine, in the factory, in the study and in the offices of the various learned professions, brain work is in constant demand, and our own State and the country at large is chargeable with the most gross neglect in failing to properly appreciate these facts and in neglecting to provide the means for meeting the demands of the age for a more practical system of education than can be obtained in our ordinary schools and colleges.

The State is amply able to meet this demand for technical schools, and the pressing importance and growing desire on the part of the public to avail itself of such advantages would fill them with eager pupils. The cost of such schools would be repaid to the State an hundred fold by the new and improved spirit which it would inspire in our shops, and, in fact, in all the various industrial walks of the community. The English and Continental nations are far ahead of us in these things, and the superior training to which European mechanics have been subjected is fast filling our workshops and factories with workmen from abroad, who are gradually crowding out our own people from the various avenues of labor where special skill is required. This ought not to be. It is the duty of our rulers to see that our labor is protected in this direction, as well as in those ways which are regulated by tariffs. The former is the cheaper and most effective mode of protecting and encouraging labor.

In referring to the importance of technical

education, a recent English exchange very truthfully says: "The whole world is now an open field of competition for the best men, and the records of engineering classes bear good testimony to the value of the special preparation they have had. The world is being made better and more comfortable to live in every day, by the quiet, persevering, and scarcely appreciated labors of engineers and chemists; and in the problems that are to be solved, where the great forces of nature and the present waste through ignorance are to be further utilized, the graduates of our scientific schools and colleges will be the men whose brains and hand will serve their fellow men to good purpose."

News in Brief.

ALL accounts indicate that thus far the crop prospects are wonderfully good in Manitoba and the Northwest.

BETWEEN 3,000 and 4,000 pounds of cherries are shipped daily from General Bidwell's orchards.

THE total number of prisoners in the branch prison at Folsom is 460. The prison is large enough to accommodate 600.

THE number of British visitors to the United States and Canada this summer promises to be unprecedented.

THE streams in British Columbia are lower than for years at this time of the year, and damage to the crops is feared.

A VETERINARY SURGEON appointed by the Supervisors of Solano county has made a tour of the farms, and reports the discovery of numerous cases of glanders in horses.

IN the City of New York alone it is estimated that there are at present no fewer than 400 millionaires, 30 of whom own from \$5,000,000 to \$50,000,000 apiece, while there are about 10 who possess from \$50,000,000 to \$150,000,000 each.

MOST of the 200 colored farm laborers who recently left Chattanooga, Tenn., for California, will come to work for J. B. Haggins, who intends to give the problem of cotton raising in this State a thorough trial. Of the lot of colored laborers previously brought here a majority are waiting on Mr. Haggins' farm for the crop to come forward.

REPORTS from a thousand correspondents of the *National Press and Bottlers' Advocate*, from all parts of the United States, in regard to the fruit crop, say: The apple crop is the largest ever known. There will be only a half crop of peaches and pears, but the prospect of a very large crop of small fruits is very good.

F. W. MARSHALL, a son of Attorney-General Marshall, has paid the Alameda County Treasurer \$53,757.53 collected from the C. P. R. Co., for State and county taxes for the fiscal years 1880-81 and 1881-82, being the full amount sued for by Alameda county for those years. This payment does not include penalties or interest.

Secure the Reduced Rate.

After the first of April, 1884, we announced a reduction of the price of the MINING AND SCIENTIFIC PRESS from \$4 to \$3 a year to all who would settle up arrearages at old rates and pay in advance thereafter. There are some who have not yet taken advantage of this offer, and we would therefore urge all subscribers still in arrears to remit what is due us to this date, at the rate of \$4 a year, and pay in advance for another term at the reduced rates for new subscriptions paid in advance.

How to Remit to this Office.

ALWAYS GIVE THE NAME OF YOUR POSTOFFICE every time you write to us for any purpose. We cannot find your name on our large lists unless you do. Also write your own name plainly, and the name of the paper you remit for.

THERE ARE FOUR WAYS BY WHICH MONEY, in payment for this paper, can be sent by mail at our risk—by a POSTOFFICE MONEY ORDER, by a REGISTERED LETTER, by a BANK DRAFT, or by a POSTAL NOTE. MONEY ORDERS CAN BE OBTAINED at the Postoffices of most of the large towns. For the small amount of eight cents you can buy a Money Order upon the San Francisco Postoffice, for the amount you wish to send us, and we will be responsible for its safe arrival. REGISTERED LETTERS.—If a Money Order Postoffice is not within your reach, ask the Postmaster of your town to register the letter you wish to send us. It costs but ten cents. Then, if the letter is lost or stolen, it can be traced. You send money in this way AT OUR RISK.

BANK DRAFTS.—A Draft upon any San Francisco, New York, or Washington, D. C. bank, we can use, if it is made payable to the order of the publishers of this paper, San Francisco.

POSTAL NOTES CAN BE OBTAINED for sums less than five dollars at all Postoffice Money Order Offices. For a Postal Note you must pay three cents, and the Postal Note must be inclosed in your letter to us. These Postal Notes are payable to bearer, and therefore ARE NOT SO SAFE AS A MONEY ORDER.

SMALL SUMS of money generally reach us in an ordinary letter, but we cannot be responsible for losses unless you send in one of the four ways mentioned above. SILVER BY MAIL.—Do not send over 25 cents in silver by mail unless you wrap it carefully, and put an extra three-cent stamp on the letter for every 50 cents in silver it contains. Failure to observe this may cause your letter to get lost.

POSTAGE STAMPS will be received in full payment or for fractional parts of a dollar for subscriptions of the denomination of one and two cents.

Address the PUBLISHERS of (and not individuals connected with) this paper, c/o 252 Market St., San Francisco.

Lost Papers.

If any subscriber fails to receive this paper promptly, after making due inquiries at the Postoffice, he is urgently requested to notify this office by letter, that we may send the missing papers, and, if possible, guard against further regularities.

Mining Share Market.

The market for mining stocks has maintained its usual quietness this week as of late. No transactions of special note have occurred. At the north end of the Comstock active prospecting is in progress at several points, and discoveries of value are liable to be made at any time. In Union Consolidated and Sierra Nevada, along the line of the main north and south drift, some 10 or 12 crosscuts have been started and run out a certain distance east and west. In several of these the diamond drill has been sent ahead for long distances. Presently a start will be made in some of these beginnings of crosscuts. West crosscut No. 4, in Union Consolidated ground, now out 20 feet, is showing a very lively mixture of quartz, clay and porphyry.

At the Hale and Norcross work has not yet been resumed on the 2800 level. Much ore is being extracted from the newly discovered body on the 200 level, and there is now in the dumps over 800 tons.

At Gold Hill the leading mines are still finding a good deal of low grade ore, keeping all the mills on the Carson river running to their full capacity. At the Alta the main west drift on the 2150 level is again being pushed ahead. The diamond drill is now in position at the face of the east drift on the 2150 level, and will be started up as soon as the diamonds arrive that were telegraphed for to New York.

Bullion Shipments.

Hanauer, May 20, \$1,950; Horn Silver, \$12,000; Hanauer, 24, \$7,410; Horn Silver, 22, \$3,000; do., 23, \$6,000; Stormont, 24, \$3,370; Horn Silver, 24, \$9,000; do., 25, \$9,000; Bodie Con., 27, \$17,228; Navajo, 26, \$3,200; Bonanza King, 26, \$7,654. The banks of Salt Lake report the receipts for the week ending May 21st, inclusive, of \$67,000 in bullion.

Coal.

From the circular of J. W. Harrison, coal and metal broker, dated May 24th, we take the following concerning cargo lots of coal: Among the transactions of the week there is nothing very encouraging to report. Imports from our Coast Collieries for the week foot up 10,350 tons; from Great Britain and Australia, 3,322 tons; among the latter arrivals is a cargo of Mount Kembla steam coal, mined about 30 miles below Sydney. It is indorsed very highly by consumers there, and this cargo has been imported with a view to its general introduction here, as a substitution for Coal Cliff and Bulli. Samples can be seen at my office.

Some few cargoes of Foreign Coal have been ordered at full figures for early loading, and some offers for more are in hand at a shade lower, which remain unaccepted, so that it may be safely predicted no lower quotations will rule for some time. Some references through the press have been made lately about Anthracite discoveries in Mexico. It will be many years, if ever, before they will make any showing in our market; their location is too remote, and samples shown are of inferior grade.

SPOT PRICES.

Scientific, Mining and Other Valuable Books.

PUBLISHED OR ISSUED, WHOLESALE AND RETAIL, BY DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1807.

This work is unequalled by any other published embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, the most complete and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1850.

This rare book on the treatment of gold and silver ore without quicksilver is liberally illustrated and contains full of facts. It is a short and concise description of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 156 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$3, copy, postage free.

One Out of a Hundred Heard From.

C. MILLER, 135 Montgomery street, desires to inform our readers that he is not the optician interviewed by the *Chronicle* reporter, issue of February 12th, as he does not claim as his own, nor require Bernier's Patent Optometer, Rochester, New York, or any other as his own invention. There are many pretenders and would-be opticians, but very few frank enough to confess it. Some opticians claim exclusive mechanical facilities for suiting the eye, and acknowledging their utter incompetency when pathological difficulties present themselves. No swindling or make-believe pretensions resorted to at my establishment. It is physical and Physiological Optics are my daily study. With over thirty years' practical experience, I can confidently solicit all who have eye difficulties to avail themselves of my professional services free of charge. C. MILLER, Optician, 135 Montgomery street, San Francisco.

Business Offices and Sunny Rooms to Let.

We have some desirable rooms to let adjoining the offices of this paper, which will be rented on favorable terms. Stair entrance, No 252 Market St. Elevator, No 12 Front St. Parties wishing offices, etc., will do well to call and see them. DEWEY & CO.

A Plain Book on Assaying.

"ASSAYING GOLD AND SILVER ORES"—By C. H. Aaron.—Is a new work published by Dewey & Co., which is intended by its author to be available for the use of miners, prospectors and others who only care to know how to assay gold and silver ores.

The author of this work is well known in the mining regions of the Pacific coast as a practical metallurgist of many years experience. His writings for the press and his two previous works ("Testing and Working Silver Ores," and "Leaching Gold and Silver Ores") have shown his ability as a writer. The little book is plainly and simply written, more especially for the use of those persons not familiar with chemistry. No symbols are used, everything being plainly stated and clearly described. The scope of the book is shown in its table of contents as follows: Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scoriafication; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables. These assaying tables give simple directions for figuring out results. This is the simplest, cheapest and most easily comprehended work on assaying yet published. The volume comprises 106 pages, with illustrations, and is well bound in cloth. The price is \$1, postpaid. Published by Dewey & Co., MINING AND SCIENTIFIC PRESS office, San Francisco—1884.

An Easy Binder.

A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held nearly as in a cloth-bound book. It is durable, and so simple a child can use it. Price, (size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co.'s journals, Harper's Weekly, and Scientific American), 85 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Books for Miners and Millmen.

KUSTEL'S CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for gold-bearing sulphurets, arsenurets, and gold and silver ores generally, with 120 lithographic diagrams. 1807. This work is unequalled by any other published embracing the subjects treated. Postpaid, \$7.50. Printed and sold by Dewey & Co., S. F.

KUSTEL'S ROASTING OF GOLD AND SILVER ORES (Second Edition, 1850), and the Extraction of their Respective Metals without Quicksilver. Illustrated. 150 pages. A valuable and carefully written work. Postpaid, \$3. Sold by Dewey & Co., S. F.

AARON'S LEACHING GOLD AND SILVER ORES, the most complete hand-book on the subject extant; 164 pages octavo. Illustrated by 12 lithographic engravings and four wood cuts. Fully indexed. Plainly written for practical men. In cloth, \$3. Sold by Dewey & Co., S. F.

MINING, ENGINEERING, MECHANICAL, FARMING, SCIENTIFIC, INDUSTRIAL, and New Books in general, can be ordered through Dewey & Co., S. F., at publishers' rates.

PHILLIPS' EXPLORERS' AND ASSAYERS' COMPANION (Third Edition). Price of Vol. 1, postpaid, \$6. Sold by Dewey & Co., S. F.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below costs, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

Iron and Machine Works.

MACBETH'S

—PATENT—

STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting.

On account of their great lightness and the form of the arms, they absorb less power than any other pulley.

They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq. — Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,

For the Mather Lane Spinning Co. (Limited),
[Signed:] RICHARD T. MARSH,
Managing Director.

Economy in space and fuel. Safety at high
pressures. Freedom from scaling. Equally
adapted for power and heating purposes.
Especially adapted for mills, factories, hotels,
stores or any place where safety is a necessity.
Will work well with muddy water and any kind
of fuel.

TESTIMONIALS.

St. Louis, Mo., Sept. 28, 1883

Messrs. Adolphus Meier & Co. GENTLEMEN:
We cheerfully certify that the "Heine Patent
Safety Boiler" put up by you in our establish-
ment has proved very satisfactory in its working.
The chief points of excellence in the "Heine
Safety Boiler" are its economy in fuel and space,
freedom from scaling, aptitude for power and
heating purposes, working equally well with clear
and muddy water. We warmly recommend it to
all using steam machinery. Yours truly,

ANHEUSER-BUSCH BREWING ASSN

OFFICE OF Supt. of RYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to
your inquiry of September 2d, we respectfully in-
form you that the three boilers built under your
patents under steam since September 25, 1881, at the Alex-
ander Place Depot, as well as the two at Friedrich Strasse
Depot, under steam since September 22, 1882, have given
good satisfaction, requiring no repairs whatsoever to date.
The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the
tube caps, the adhesion of scales being fully prevented
thereby, and the boilers kept in prime condition.

(Signed): BRAUCKE.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

OUR U. S. AND FOREIGN PATENT AGENCY presents many and important advantages as a Home Agency over all others, by reason of long establishment, great experience, thorough system, intimate acquaintance with the subjects of inventions in our own community, and our most extensive law and reference library, containing official American and foreign reports, files of scientific and mechanical publications, etc. All worthy inventions patented through our Agency will have the benefit of an illustration or a description in the MINING AND SCIENTIFIC PRESS. We transact every branch of Patent business, and obtain Patents in all countries which grant protection to inventors. The large majority of U. S. and Foreign Patents issued to inventors on the Pacific Coast have been obtained through our Agency. We can give the best and most reliable advice as to the patentability of new inventions. Our prices are as low as any first-class agencies in the Eastern States, while our advantages for Pacific Coast inventors are far superior. Advice and Circulars free.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or lift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep—the bottom all in talc and white porphyry, streaked with veinlets of quartz speckled with ore. This mine is 1 1/2 miles northeasterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize excelled by none—yes, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

Foreign Patents.

The number of years in which patents are granted varies in different countries, and in nearly all are affected by conditions, the fulfillment or non-fulfillment of which cannot possibly be known to our own Patent Office, notwithstanding which fact inventions patented abroad are only patentable in this country for terms concurrent with the value and duration of the foreign patent. Much confusion naturally arises out of this condition of things, but its most serious effect is felt by innocent purchasers of patents which have lapsed or may lapse with the termination of a foreign right of which they have no knowledge. The Commissioner of the Patent Office of the United States has suggested proper legislation to fix a definite term for patents upon articles or devices that have first been patented in foreign countries; and considering the fact that the terms for which patents may be granted in foreign countries are shorter than those for which they may be originally granted in this country, he suggests that 12 years would be a proper term for patents when the invention has first been patented, or a patent applied for, in a foreign country. The difficulty now experienced in Patent Office practice would be thus removed, and a necessary certainty obtained. Many of our inventors do not seem to have a true appreciation of the value of foreign patents, and content themselves with protecting their inventions in this country alone. The European countries are very densely populated, and there are hundreds of our United States patents which, if known there, would bring large returns to the owners. People who have made successes of their inventions in America should consider the fact that a few hundred dollars expended in obtaining foreign patents may bring them in much more than they get in this country. As a general proposition, when a man patents in this country a good practical invention it will pay him to select two or three foreign countries and procure patents in them also. The MINING AND SCIENTIFIC PRESS Patent Agency is prepared to give all the necessary information and to procure patents in all countries in the world. England is generally selected first, on account of its large centers of population and the opportunities for quick sale of the patent right or the article itself. Germany, too, is a good place for American patents. The Australian Colonies are quite often selected by Pacific Coast people because of our trade with those regions. It depends, of course, on

the nature of the invention as to the best countries in which to obtain the patent. We shall be pleased at any time to give information as to the cost, requirements, etc., of the different countries of the globe where American inventors care to patent their inventions.

Academy of Sciences.

Professor Davidson has been suddenly called to Washington. Vice-President Harkness presided at the meeting of the Academy of Sciences on Monday evening last. Richard H. Sinton was proposed as a resident member, and A.

The Wheelock Engine.

The Wheelock Engine, illustrated on this page, is the type which took the grand prize at the Paris Exposition and also first prize at the Millers' Exposition in Cincinnati, where severe practical tests were made. The elaborate valve-gearing, characteristic of most variable cut-off engines, has been simplified in the Wheelock so as to obviate this objection. The engine has many qualities to recommend it to the mining and manufacturing interest on this coast. Among these are its simplicity of construction and perfect automatic action. No special

with the determined yet adjustable point of expansion, combine to produce economical effects. The cylinder has but two ports, steam being admitted and exhausted by a single valve. The steam chest and valves are located beneath the cylinder, which prevents any trouble from water. All adjustments, both of the main and cut-off valves, are made on the outside of the steam chest, and are therefore accessible for repairs when necessary. The patent steam piston packing is a prominent and valuable feature of this engine, by which the friction and wear of the cylinder is materially reduced and the adjustment so perfect as to prevent absolute-

ly all loss of steam. Syphon condensers can be attached where water is accessible, with a saving of fully 30 per cent. The high rate of piston speed at which these engines can be run makes the duty of any given size relatively high, thus making a saving in first cost as well as in transportation and erection. The proportions are also much heavier than Eastern made engines, while the general design and detail of construction are in accordance with the most advanced practice, and adapted to the kind of duty demanded on the Pacific coast. Among the many engines of this type sent out by Rankin, Brayton & Co., of the Pacific Iron Works, of this city, are those at

THE WHEELOCK AUTOMATIC CUT-OFF ENGINE.

Pierce as a life member. A paper on "A Mechanical Test for Coal" was read by Melville Attwood, extracts from which appear in another column.

Prof. A. M. Bell, of Washington, inventor of the Bell telephone, explained his invention, which he called visible speech. It consists of signs representing sounds, the signs indicating the position in which the tongue and lips must be placed to make the sounds. The speaker stated, as an illustration of the accuracy with which the signs could be read and translated into sound, that if anyone were to speak a word in the Indian language, or any other language foreign to him, he, or any expert could write the word by the signs, so that another expert, who had never heard or seen the word could instantly speak it.

General Houghton said that Prof. Bell's system was being tried in the Berkeley Institute for the Deaf and Dumb.

Dr. H. Hernau Behr showed a phylloxera insect in the gall on a grapevine leaf, seen through a common magnifying glass, the first of the kind ever exhibited in the Academy.

THERE are between twenty-five and thirty logging camps in operation on the Skagit river and its tributaries in Washington Territory.

mechanical skill is necessary to run them, as they are run with an open throttle and under all conditions of load or pressure, are completely under the control of the governor. They are also provided with an automatic stop-motion, so that in case of derangement to the governor or attachments, the engine is immediately brought to a standstill.

Regarding economy of working, exhaustive and thorough tests have been made in various places during the past few years with satisfactory results. The special claims made for this engine, simplicity of construction, durability and economy of operation, are elaborated more fully in the following details:

The valves do not rest on their seats, but are partially suspended on hardened steel trunnions, and are therefore free from friction and handled without resistance, the effect being the same as steam balancing, without the objections that apply to that method. They are also tapered and self-adjusting to compensate for wear, and by an ingenious arrangement of the journals and bearings are made self-packing and thus require no stuffing boxes. The clearance is reduced to a minimum by the use of but one port at each end of the cylinder.

The positive movement of the main valves and the quick motion of the cut-off valves, together

work in the following places: Yosemite Flour Mills, Bay City Manufacturing Co. and Detrick Bag Factory, San Francisco; Judson Manufacturing Co. and Oakland Hosiery Co., Oakland; Crown Mills, Stockton Agricultural Works and Buell Planing Mills, Stockton; Hollister Flour Mills, Hollister; San Jose Flour Mills, San Jose; Chico Flour Mills, Chico; and Portland Milling Co., Portland, Oregon.

At the last meeting of the Geographical Society it was ordered that the report of the Committee on Shoaling of the Bay be taken from the file and the lecture of Professor Davidson added, and the whole be adopted as the sense of the association. J. Finlay Finlayson read an interesting paper on "British Guiana—Its Past, Present and Future."

The town of Murray at the Coeur d'Alene mines bids fair to be the leading one in that section. The newspaper has been moved from Eagle to Murray, which town is in the center of the producing mines.

RICHARD H. SAVAGE has retired from the firm of Savage & Sons, and a new partnership has been formed under the name of Savage, Son & Co., consisting of Richard and John Ewart Savage and George Monroe Pinckard.

Some Researches on the Amalgamation of Gold and Silver.

The following paper was read before the American Institute of Mining Engineers, by T. Eggleston, Ph. D., N. Y.:

In the year 1881 I presented to the Institute two papers containing the results of researches on gold, in which I endeavored to make plain some of the causes of the losses in the working of gold ores. Since that time I have continued this investigation at intervals with the following results.

In the papers previously presented to the Institute I made no attempt, to make compounds containing more than two substances. Since then I have endeavored to make more complex compounds. The experiments consist in fusing mispickel free from gold with a certain amount of metallic gold, and experimenting with that; also fusing the same mineral with sulphide of antimony, and fusing iron pyrites with gold and compounds of antimony.

The mixture was made with mispickel taken from a vein not far from Stamford, Conn., absolutely free from gold. It was fused with gold in a crucible, reduced to powder, carefully roasted, sampled and assayed, and found to contain 143 ounces of gold to the ton. This mixture was then amalgamated in an iron vessel, without chemicals, with clean mercury, and by this method 36 ounces, or 25 per cent, were extracted, and 107 ounces were left in the tails. It was then amalgamated with a neutral solution of bichloride of mercury in an iron vessel, and 11 ounces, or 7.5 per cent, were extracted, and 132 retained in the tails, making a total of 32.5 per cent extracted.

Another sample was treated with mercury and an acid solution of bichloride of mercury in an iron vessel, and 13 ounces or 9 per cent, were extracted and 130 left in the tails, the acidity of the solution having produced no effect. An electric current was then passed through a sulphuric acid solution with mercury; 23 ounces, or 16 per cent, were extracted and 120 left in the tails, or 25 per cent altogether extracted.

A fresh sample was then treated with cyanide of potassium and mercury in an iron vessel, and 62 ounces, or 43.3 per cent, were extracted while 81 ounces were left in the tails. These tails were then re-amalgamated with cyanide of potassium; two ounces were extracted and 79 left in the tails. These tails were again re-amalgamated with salt, bichloride of mercury, and mercury, and two ounces, or in all 46 per cent were extracted and 77 ounces were left in the tails.

After Repeating These Experiments

A number of times the conclusion was drawn that on artificially prepared substances such as these, made by fusion, the most careful and prolonged roasting did not sufficiently destroy the combinations of gold, or more probably the coating of oxide of iron on the gold, so as to enable the mercury to reach it even when bichloride of mercury was added with a neutral solution and no advantage was gained by treating such an ore with bichloride of mercury, even in an acid solution; and that even with cyanide of potassium, which acted the most powerfully of all the chemicals, the amount of loss would necessarily be very large, and that it is consequently dangerous in roasting ores of gold containing sulphur and arsenic ever to allow a high temperature in the furnace. The amount of sulphur contained in the roasted ore was not determined chemically, but it was quite small, and so was also the amount of arsenic. The roasting was prolonged and very carefully done, every precaution being taken to prevent such an elevation of the temperature as would cause the ore to frit, and every effort was made to have the processes conducted exactly as they would have been in a mill.

Sulphide of antimony, free from gangue, was then mixed with the pulverized arsenopyrite, and fine sponge gold added to it, and the whole fused in a crucible. It was then pulverized, roasted and assayed, showing \$516.72 to the ton. It was then treated in an iron vessel with cyanide of potassium and mercury. The tails assayed \$69.27, showing that 88 per cent of the gold had been extracted.

Another sample of the same ingredients was melted in a crucible, and assayed 249.5 ounces to the ton after amalgamation. The tails contained 57.7 ounces, showing that only 76.9 per cent of the gold had been extracted.

Pulverized iron pyrites, stibnite and gold were then fused together, carefully roasted and assayed 56 ounces to the ton. The roasted ore was then amalgamated with cyanide of potassium in an iron vessel, and 9.1 ounces were extracted. The tails were then amalgamated with bichloride of mercury and mercury in an iron vessel, and 4.8 ounces extracted, or 13.9 ounces altogether, showing an extraction of only 24.82 per cent. As a microscopic examination showed a very few exceedingly small spots of undecomposed pyrites, it was thought best to repeat the experiment. Another mixture was made, which, after roasting, assayed 120 ounces to the ton. The roasting was done with the greatest care at a low temperature. After the fumes ceased to be given off, powdered charcoal was added to reduce any oxidized compounds. The excess of charcoal was burned out at as low a temperature as possible. Only 25.36 ounces were ex-

tracted, or 21.14 per cent, thus confirming the previous experiment. Up to this time I had never been able to obtain from any of the mines a

Mispickel Containing Gold.

Since the Troy meeting of the Institute, I have, through the kindness of Messrs. Rothwell and Platt, obtained some. The raw ore contained 14.17 per cent of sulphur, and 20.50 per cent of arsenic. The roasted ore contained 0.67 per cent of sulphur and 1.87 per cent of arsenic. The assay of the roasted ore showed it to contain \$67.88 per ton in gold, and \$5.17 in silver. On treating it with cyanide of potassium and mercury in an iron vessel the tails were found to contain \$14.16 of gold and \$3.67 silver, so that 75 per cent of the gold, and only 30 per cent of the silver was obtained by this process. This treatment of the roasted ore was much more successful than with the material which had been fused, and shows the necessity of avoiding high temperatures in roasting gold ores. It is evident that without the

Use of Expensive Chemicals.

under conditions artificially produced there is something which prevents the amalgamation when arsenic, antimony, and sulphur are together in the ore. Exactly what this is I have not yet been able to ascertain, but hope at some future time to be able to announce to the Institute exactly what the conditions are, which when sulphur, antimony, and arsenic are present, prevent the gold from being attacked by the mercury; but I have little doubt that it is for the most part a coating formed during the roasting, and that the imperfection of the trials is owing to the same cause, and to the very small quantities necessarily used in the laboratory tests.

As in the Konoake meeting of the Institute doubt was thrown on the experiments on the non-amalgamation of hardened gold, I have renewed them with great care. A neutral solution of corrosive sublimate will scarcely attack gold at all under any conditions whether hard or soft. I have repeatedly tried the experiment of placing the pieces of gold in a neutral solution and touching them with a point of iron, such as a knife blade. The blade of the knife became invariably corroded, and amalgamation sometimes took place at the point where the iron touched the gold, but spread no further even after prolonged contact with the iron. When this same soft gold was placed in an acid solution and touched with an iron point, the amalgamation took place instantaneously. When, however, the gold which has been hardened by heating on an anvil, is subjected to even the acid solution, it amalgamates very slowly, even with prolonged contact with the salt of mercury. Through the kindness of Tiffany & Co. I obtained

Samples of Pure Gold

And of gold alloyed with copper. These samples were first rolled until they were extremely hard and then were hammered on an anvil and were placed in contact with mercury. After a considerable time they began to amalgamate very slowly. Samples of the same gold were then annealed in an ordinary Bunsen flame, after which annealing they became perfectly black and would not amalgamate at all under any conditions, owing to the formation of an oxide of copper upon the surface of the metal which prevented contact. When, however, the original alloy and also the alloy annealed was treated in nitric acid they both amalgamated with equal readiness. It appears therefore that not only will fine gold which is hammered be prevented from amalgamation, but that the ordinary alloys of gold will also be prevented equally from amalgamation. When fine gold, as I stated in my previous researches, is hammered, it does not amalgamate; but when it is annealed, it will immediately amalgamate. This appears not to be the case with all alloys, where there is an opportunity in the course of annealing for an oxide to be formed. In order to reproduce the

Conditions in Which Metallic Gold is Found

in the stamp mills, strips and pieces of gold were pounded in a perfectly clean iron mortar with a clean pestle in as nearly as possible the same conditions as they would be in an ordinary stamp mill. It was found that when the stamping was done under water and with light blows, and for only a short time while there was an evident increase in the difficulty of amalgamating, the gold did amalgamate with sufficient readiness to insure that the most of it would be caught by the mercury after prolonged contact. When, however, the blows were very heavy and the pounding continued for some time so as to flatten out the piece, prolonged contact with the mercury produced only a very slight amalgamation, which did not even show the smallest trace under five minutes, and was only partial even after half an hour. Every attempt was made to make the mercury attack this gold. It was placed directly in and on it, but the quicksilver rolled over and over as if the gold had been so much sheet iron. Even when the mercury commenced to adhere to the gold it was in very minute spots which did not spread for a long time. When a piece of the same metal was treated with acid, there was a perceptible difference in the rate of amalgamation; but it was still very slow, too slow for the amalgamation of an ordinary stamp mill. When these same pieces were annealed

they amalgamated immediately. The same operation was repeated on pieces pounded in a mortar without water. The amalgamation took place even more slowly than before. When the pieces were cleaned with acid they amalgamated about as slowly as the pieces treated under water which had not been cleaned. It took a much longer time to produce the adherence of the fine globules of mercury, and they propagated themselves much more slowly. In every case where a freshly broken edge came in contact with the mercury it was attacked at once, showing that a film had been formed which prevented contact. This film is slowly dissolved by acids and quickly dissipated by heat, for when they were annealed the pieces amalgamated at once. The same results were obtained when the gold was heated on a dusty anvil. The same experiments were

Tried with Silver.

Pieces, obtained from an assay, which were consequently nearly pure, were pounded in a mortar, some with, others without water. Those in which the water was used presented a perfectly clean appearance, somewhat duller than the ordinary color of silver, and when made into a small dish and a globule of mercury placed upon it, it retained the mercury for a considerable length of time without being affected by it at all. When the mercury was placed in a vessel, and the silver dipped in it, it did not attack it all at first, but after considerable agitation and rubbing against the sides of the vessel an attachment was made on the edge. When this edge was broken the mercury attacked the fracture at once, very fine globules being disseminated all over the edge. Notwithstanding this the surface resisted the contact of the mercury for a considerable length of time, and then was only irregularly attacked. When the piece was treated in diluted sulphuric acid for some time, and then cleaned and treated with mercury, it resisted in the same way, but for a shorter time. When this piece so cleaned was annealed in a Bunsen burner, the mercury attacked it instantly.

The pieces which had been pounded in the mortar without water had a much darker appearance in patches unevenly distributed over the surface of the piece. It resisted the action of the mercury for a great length of time, but when placed in a vessel with the mercury and treated with sulphuric acid, it acted in about the same way as the piece pounded under water did before being cleaned. It would have taken a very long time to have amalgamated the whole of this piece. When the cleaned pieces was, however, annealed and placed in the mercury it amalgamated like all the others instantly. It thus appears that silver as well as gold is

Affected by Pounding.

And that under the most favorable conditions, where no foreign material is present, it will amalgamate with very great difficulty. When, however, any foreign material, as dust or small particles of ore had been allowed to remain in the mortar or on the pestle, the amalgamation took place even more slowly than before, and in some cases after a number of hours, no perceptible effect of the mercury could be observed. That this coating is a superficial one, that amalgamation is possible where there is a freshly broken edge, and that this amalgamation on the edge will eventually extend through the whole piece, and that the pounding of the pieces is undoubtedly a source of loss in the mills, these experiments seem to settle decisively.

It is well known to silversmiths that when silver is annealed after being hardened it turns black, and that when this is placed in the pickling acid the black substance is dissolved upon the surface and it becomes perfectly white. When, however, this white coating is brushed into, there appears below it a purple coating which is composed of the oxides of copper and of silver, and this purple coating cannot be removed except at considerable expense. A microscopic examination of the coating shows that when the pickling acid attacks the coating of oxides, it does so only superficially, leaving a porous coating, which when highly magnified shows the oxide below. As the oxides are lodged in the bottom of the lines of the scratches which are produced by the polishing, the decomposition of the light gives appearance of a purple color. When, however, the objects are highly magnified, only the white color of the pure silver and the brown in the bottom of the depressions of the scratches are seen. It seems probable that similar oxides form upon gold alloys and prevent the contact of the mercury.

Discussion.

R. P. Rothwell, New York City: I have been treating arsenical pyrites for some time. I have made a good many tests, covering perhaps a thousand or fifteen hundred tons of mispickel ores, treating by amalgamation in pans, and I do not find the difficulty that Dr. Eggleston has suggested in roasted ores. On the contrary, I was able to get over eighty, up even to eighty six per cent of the gold from roasted mispickel. If Dr. Eggleston had confined his remarks to raw mispickel, I think he would have expressed about what I found to be true in treating the raw ores by amalgamation, but in the roasted ores you can get out a very large percentage.

The percentage that can be amalgamated in raw mispickel will probably not exceed 30 to

40. The reason for this, I am not able to state; but Mr. Riotte of Mathey & Riotte, of New York, who tested some of our mispickel ores, told me that he had examined it with a microscope, and that the gold in it was what you would call coarse gold, though to the naked eye the gold seemed pretty fine, yet under the glass it was comparatively coarse gold. As far as he could see with the microscope, it stopped suddenly at a certain line and beyond that he found no fine gold. Even though he pulverized it very finely in a mortar, he could find no more free gold in it. He then assayed this remaining mispickel that had not apparently any gold in it, and he found, as he told me, very uniformly about \$20 per ton in it, that was in the condition of what he called "combined gold." I do not know whether that is the reason that it did not amalgamate, but I know that the arsenic has something to do with it, and that this is very injurious in amalgamation by reason of flouring the quicksilver; but when you roast these ores, even though you are unable to get out all the arsenic, there is no difficulty whatever in getting at least as perfect an amalgamation as you do from free gold-ores generally. When we extracted that percentage, the roast was made in a revolving cylinder, 24 feet long, and it was not so perfect a roast as is necessary for chlorination, and yet we got that high percentage. When the ores are thoroughly roasted, although they still contain some arsenic, which you find in solution after chlorination, they will amalgamate up to a very high percentage. The average of the first eight hundred tons that I treated by chlorination gave about ninety-four and a half per cent, and it ran up to ninety-eight and even ninety-nine per cent, fire assay, that we would get out by leaching the chlorinated ore. But chlorination requires a more perfect roast than amalgamation. I see, nothing, therefore, in the arsenic that interferes with chlorination, nor with amalgamation, if you roast the ores well; though you never get rid, as I say, of all the arsenic, which you find again in the solution, where it produces new complications, which the professor has not referred to and which it is not necessary to mention.

NEW MEXICAN MINES.—Things look a little gloomy in the east and not very flattering accounts come from Arizona, but a brighter outlook for the mining industry has never dawned upon Grant county. With improved machinery for the treatment of our low grade ores this section of Grant cannot but come to the front. When miners have ready sale for their product they will set to work upon their properties with a vim. Hundreds of claims upon the dumps of which ore has been lying for years past will be operated under the new order of things, and the thump of the hammer and echo of the blast will be familiar sounds. The attention of the mining men from abroad is being attracted by the flattering returns from some of the mines at present in operation, and daily, men who are desirous of investing are coming among us. It is true that the outrageously high prices asked for many of the claims offered for sale tend to drive many capitalists out of the country. The experience derived the past year will work to the advantage of the prospectors of this country, in convincing them that they cannot dispose of their prospects at fabulously high prices unless great merit can be shown. Fair prospects are numerous and prospectors, with the advantages offered by local reduction and sampling works, can find ready sale for their ore in small or large quantities, thereby developing their claims at small cost, if not to a profit, and placing them in a condition to invite capital. The sooner an owner discovers a claim to be worthless, the better for him.—*Silver City Enterprise.*

THE SWEETWATER MINES.—L. J. Hill, H. E. Wright, Jas. F. Norman, Wm. Shirley and John Poor returned on Monday from a visit to the Sweetwater mines. Mr. Shirley, a prominent millman of Dayton, Nevada, and formerly superintendent of the Bodie Tunnel mill, went to examine the Kentuck mine, while Messrs. Hill, Wright and Norman paid a visit to their leading mine, the Silverado. This mine is employing a force of nine men, under the superintendence of Thomas Downing, and is showing up some very fine ore. The mill, now in process of construction to run on ore from the Silverado, will be ready for operation by early July. The mine is being rapidly put in shape for taking out ore. It is attracting considerable attention, and bids fair to become one of the leading mines of the district. The men employed in the Kentuck on percentage are doing well, and are taking out some really fine ore. The mill will start soon, either on tailings or on ore from the mine. Several other mines in the district are working men, and others only await the disappearance of snow from the mountains to resume operations. The opinion is very prevalent in Clinton that the Kentuck mine is not yet even prospected, and all are hopeful for a prosperous season.—*Bodie Free Press.*

THE ARANTRA BUSINESS.—Below the Green Mountain mill the Italians have thirteen large water aras, which work steadily day and night on the mill tailings. For these they pay the company a certain sum per ton, and what they make is known only to themselves, but that they make the tailings pay something is certain, or they would not continue the business.—*Cor. Plumas National.*

MECHANICAL PROGRESS.

Uses of Aluminum.

Aluminum bids fair at no very distant time in the future to prove a metal of considerable importance in the arts. Just now its high price is a bar to any very extensive introduction of this metal into general use. Chief Engineer Latimer, of the New York, Pennsylvania and Ohio road, in a paper recently read before the Civil Engineers' Club at Buffalo, said that the time might not be far distant when rails of aluminum would take the place of steel, as, according to a recent report, it had been announced that aluminum could be produced for about the same figure that steel rails formerly cost. One writer claims that this metal can now be produced at twenty cents a pound. It has doubtless the strength of iron, but its chief excellence is its non-corrosive properties. The rails of the present rust out almost as rapidly as they wear out. Indeed, if aluminum can be produced at the figure above stated, there is no reason why it cannot be used in plating the iron work of bridges, which thus treated would look like massive works of silver.

For electrical use, as wire, Prof. Jamaisson, at a recent meeting of the Philosophical Society at Glasgow, Scotland, said he had found that the aluminum had 1.96 times the resistance of the copper wire of the same gauge and length, and but little more than half the resistance of pure copper for the same length and weight. The conclusion arrived at, therefore, was that aluminum had by far the least resistance of any known metal for its weight.

In the course of his investigation he had elicited a very curious fact, namely, that the introduction of a very small percentage of aluminum into copper not only raised its tensile strength immensely (the specimens shown having a breaking stress of about 45 tons per square inch), but also enormously increased its resistance. So far as his tests had gone, the specimens shown had a resistance of 25 times that of pure copper. He pointed out the probable uses of such wire, as, for example, in the construction of high resistance coils. Other qualities might be found well adapted for telephone wires, and the purer kinds of aluminum, owing to the great lightness of the metal, could be used for military purposes, in which lightness of baggage is an important desideratum.

A NEW ALLOY.—Notwithstanding the perfection to which various metallic alloys have been brought, says London *Iron*, some of them develop defects when applied to certain purposes which it has been sought to remedy in others, but not always successfully, or if so, probably with the development of a defect of a different character. Long familiarity with the casting and working of metals and their alloys, more especially as regards German silver, led Messrs. Henry Wiggin & Co., of Birmingham, to turn their attention to this subject, and they have succeeded in producing a new metal which they have registered and named Silveroid. This is a white metal, in the production of which cadmium, one of the rarer metals, little known in the arts, is employed. Beyond this, however, there is a special method of treatment at a certain point in the manufacture which is the secret of success. The result is a metal of great whiteness, brilliancy, closeness of grain and tensile strength, as some samples by us show. This alloy is designed to suit every purpose and process of metallurgy, and has the additional recommendation of being offered at a price which is very low when compared with its merits, and which, other things being equal, will bring it rapidly into good demand. This new alloy is not specially recommended for the manufacture of light goods of the electro-plate class. It is mainly intended to take the place of alloys of the brass, bronze and gun-metal classes, in fact, of every inferior metal, where color, polish, weight and richness of luster are desirable. We learn that it is already being employed for railway carriage fittings, steamship furniture, harness mountings and carriage ornaments, for which, and other cognate purposes, it appears to be admirably suited.

IS PUDDLING NECESSARY.—A comparatively new process in the manufacture of low carbon Bessemer steel, says an exchange, was tried a short time ago at the works of the Pittsburgh Bessemer Steel Co., which, if after sufficient trial, is found successful, will completely revolutionize the work of puddling, doing away with that process altogether. Heretofore but little Bessemer steel has been made below a certain degree of carbon, which renders it impracticable to use for many purposes for which wrought iron is employed. But my late experiments under the present management, by the above works, steel is expected to be made as low in carbon as 1.600th of 1 per cent, which, the superintendent states, will answer all the purposes for which wrought iron is used.

TESTING STEEL RIVETS.—The following are the latest instructions issued by the British Admiralty for testing steel rivets: The rivets are to be made from steel bars having an ultimate tensile strength of not less than 58,000 pounds per square inch of section, nor more than 67,000 pounds, with a minimum elongation of not less than 20 per cent in a length of eight inches. A portion of one bar in every fifty to be taken for testing before being made into rivets. Pieces cut from every bar, heated uniformly to a low cherry red, cooled in water at 82° F., must

stand bending in a press to a curve of which the inner radius is equal to the radius of the bar tested. Rivets are to be properly heated in making, and the finished rivets to be allowed to cool gradually. The rivets are to stand the following forge tests: (1) The shank to be bent double cold, without fracture, to a radius equal to the radius of the shank. (2) Bent double hot, to as small a radius as possible. (3) Flattening of the rivet-head while hot, without cracking at the edges—the head to be flattened until the diameter is 2½ times the diameter of the rivet shank. (4) The shank of the rivet to be nicked on one side, and bent over to show the quality of the material.

STEEL CASKS.—A Wolverhampton (Eng.) firm has turned its attention to the manufacture of casks and barrels of steel. The two edges of the sheet of steel which form the cask are brazed together in such a manner as to justify the title of "seamless," which the patentees have applied to these productions. The head of the barrel is also riveted to the body, so as to leave no seam, and the end rims are shrunk on hot, thus making a very solid end, whilst, at the same time, the rims are thick enough to give a good purchase to the grappling-hooks of boats and cranes for loading and unloading purposes. The hush for the tap does not project beyond the rim, so that the nozzle is not liable to be knocked about and injured. The casks are more durable than wood, less bulky and lighter—on 18 gallon steel cask weighing some 10 pounds less—a not unimportant consideration as regards transit. In point of shape, a steel barrel is exactly that of a well-formed wooden one, the bulge of the belly allowing of its being easily rolled along, and better managed by one man than drums can be by two.

THE ANCIENTS.—Nothing could better illustrate the complete ignorance of the ancients as to the true nature of steam, the pressure of the atmosphere and the significance of a vacuum, than this simple toy, the notion of which any schoolboy of to-day can explain. It was a favorite subject for contemplation and wonder to the philosophers of the period. They never tired of watching it and framing elaborate and pompous explanations of its laws of action, which, stripped of verbiage, simply amounted to saying that it worked because such was the nature of things it couldn't help it. Of the real rationale of the process involved they had not the slightest conception. The very existence of the air as a heavy superincumbent fluid, pressing upon everybody and everything with a force of 15 pounds on every square inch of surface, of steam and its laws, even the true idea of what constituted a vacuum, these were then mysteries which had to wait for Galileo and Torricelli to unravel.

A LONG STRAIGHT EDGE.—An absolutely exact straight edge of more than thirty-six inches is a wonder of mechanism. One of six feet was not recently believed possible, although several had been made on different plans of web-like and truss construction. It has been claimed, however, that almost exactness has been secured by a straight edge twelve feet long. The appliance looks like an arched truss, the highest spring of the arch being only twenty inches in a length of twelve feet. The space between the cord and spring is filled with diagonal lattice work. Three of these straight edges have been made, one remaining in the establishment where built, and two going to technical colleges. Each of them has been tested by each other, and proved to be practically perfect. —*Scientific American*.

FRICTION.—Professor Thurston states that the coefficients of friction of lubricated surfaces under pressure, as given in text books, are much too high. Instead of four to seven per cent, as stated therein, he has obtained as low as one-fourth of one per cent with sperm oil. This, he says, is the best he ever found for heavy pressures, and he has made experiments all the way from very light up to 1,500 pounds per inch of surface. The crank pins of beam engines on steamboats, where a thousand pounds pressure to the square inch is not uncommon, run as low as one-half of one per cent for friction.

PROPORTION OF DEFECTIVE BOILERS.—A matter for serious consideration is the April report of the inspection of steam boilers at Hartford, Conn. The report gives 3,066 defective steam boilers out of 4,770 inspected, 491 of them being considered dangerous. The reckless manner in which boilers generally are used is really frightful, and the only wonder is that explosions and other accidents (!) are not more numerous than they are. It certainly is a compliment to boiler makers that the work they turn out hears so much abuse without breaking down or going up.

SOLAR HEAT MACHINES IN ALGERIA.—The French inventor who some time ago patented a machine for the use of concentrated solar rays as a general motive power has set up three of his machines in Algeria for the French government. He is now carrying on his experiments at the Island of Porquerolles, near Hyeres, in France, where he is thrashing Indian corn and raising water by the action of the sun's rays. It is not stated how much work he is able to accomplish though.

BETWEEN pure soft lead and glass hard crucible steel there are sixteen grades of hardness in tin, lead, copper, cast and wrought iron and steel.

SCIENTIFIC PROGRESS.

A Seven Thousand Mile Talk.

We have become quite familiar with reports of long talks over the telegraph wire by the use of the telephone, and of still much longer talks by means of the usual signals; but we have noticed a report of the latter character from the London *Telegraphist* which we believe exceeds anything of the kind heretofore accomplished. This long talk was accomplished between two persons 7,000 miles apart. This, to the uninitiated, will doubtless appear to be a marvel, and it is indeed a marvel—of science. Even to many a telegraph operator it may seem remarkable that direct communication can be effected over such an enormous distance. Nevertheless it is a fact, as testified by the editor of the *Telegraphist*, who gives his personal experience in an interesting article in his journal. He tells us that he had often heard of the wonderful line between this country and Teheran, the capital of Persia, a distance of 3,800 miles, but had scarcely realized the fact that good signals were obtainable through so great a length of wire until recently, when he availed himself of an invitation from the managing director of the Indo-European Telegraph Company, to make a visit of inspection. It was made on a Sunday evening, and he was first shown the Morse Printer in connection with the main line from London to Teheran. At starting, the editor was informed that he was through to Emden, and having asked a few questions of the operator in that German town he was put through to Odessa, and in a few minutes later to Teheran. Kurrachee was next spoken with, and afterwards he had a few minutes chat with Agra. To complete the telegraphic triumph, Agra switched the Old London Broad Street Station on to another line, and in a few minutes the editor was talking with a native operator at the Indian government cable station, Calcutta! At first the gentleman "at the other end of the wire" could not believe that he was really in direct communication with the English capital, and he exclaimed in Morse language: "Are you really London?" Truly this was a great achievement. Metallic communication without a break from old Broad street, London, to the telegraph office in Calcutta! 7,000 miles of wire! The signals were excellent, and the speed attained was about fourteen words per minute.

Dry Sulphuric Acid.

To make this corrosive liquid more portable and less risky in transportation it is proposed by the German chemists Vorster and Grunberg to add to it an absorbing material in the same manner as nitro-glycerine is mixed with absorbent earth. They have succeeded in carrying out the plan, and as the absorbent "kieselghur" (an infusorial earth chiefly consisting of silica), well dried and finely powdered.

It will absorb three times its own weight of sulphuric acid of 65 degrees B. In this condition it can be transported in lead lined vessels of iron or wood without any risk. For many purposes the powder may be used direct, but in some cases it must be removed by a washing of the powder, and it is asserted that "kieselghur" does not in any way contaminate sulphuric or the other mineral acids by dissolving, and that after the removal of the acid it may be dried and again used with perfect success. In this connection we may refer to the important fact that manufacturers of sulphuric acid are very generally realizing the advantages of manufacturing that product from pyrites instead of sulphur. This fact is shown from the statement that out of a total of about sixty acid works now in operation in the United States, nineteen of that number are now using pyrites, two more are almost ready to begin to burn it, and at least five have decided to erect the suitable plant. Of those now using it, one works is at Portland, Me.; one respectively at Everett, South Wilmington, North Weymouth, and New Bedford, Mass.; one at Bridgeport, Conn.; one in St. Lawrence County, and one at Hunter's Point, N. Y.; one at Bergen Point, one at Camden, and two at Elizabeth, N. Y.; one at Philadelphia, Pa.; one at Baltimore; two in South Carolina, at Beaufort and at Port Royal; one at Atlanta, Ga.; one in Chicago, and one in Detroit. The two additional works which are soon to commence burning pyrites are both in New Jersey. It is gratifying to note this rapid progress which promises to form the basis of a very large mining industry. Why should not the pyrites of California be thus utilized?

Science and Religion.

While the beliefs to which analytic science leads are such as do not destroy the object matter of religion, but simply transfigure it, science, under its concrete forms, enlarges the sphere for religious sentiment. From the very beginning the progress of knowledge has been accompanied by an increasing capacity for wonder. Among savages the lowest are the least surprised when shown remarkable products of civilized art, astonishing the traveler with their indifference. And so little of the marvelous do they perceive in the grandest phenomena of nature that any inquiries concerning them they regard as childish trifling. The contrast in mental attitude between the lowest human beings and the highest human beings around us is paralleled by the contrasts

among the grades of these higher human beings themselves. It is not the rustic, nor the artisan nor the trader who sees something more than a mere matter of course in the hatching of a chick, but it is the biologist, who, pushing to the uttermost his analysis of vital phenomenon, reaches his greatest perplexity when a speck of protoplasm under the microscope shows him life in its simplest form, and makes him feel that however he formulates its processes the actual play of forces remains unimaginable. Neither in the ordinary tourist, nor the deer stalker climbing the mountains above him, does a highland glen rouse ideas beyond those of sport or of the picturesque; but it may, and often does, in the geologist. He, observing that the glacier-bounded rock he sits on has lost by weathering but half an inch of its surface since a time far more remote than the beginnings of human civilization, and then, trying to conceive the slow denudation which has cut out the whole valley, has thoughts of time and power to which they are strangers—thoughts which, already utterly inadequate to their objects, he feels to be still more futile on noting the contorted beds of gneiss around, which tell him of a time, immeasurably more remote, when far beneath the earth's surface, they were in a half melted state, and again tell him of a time immensely exceeding this remoteness when their components were sand and mud on the shores of an ancient sea. Nor is it in the primitive peoples, who supposed that the heavens rested on the mountain tops any more than in the modern inheritors of their cosmogony who repeat that "the heavens declare the glory of God," that we find the largest conceptions of the universe or the greatest amount of wonder excited by contemplation of it. Rather it is in the astronomer who sees in the sun a mass so vast that even into one of his spots our earth might be plunged without touching its edges, and who by every finer telescope is shown an increased multitude of such suns, many of them far larger. —*Herbert Spencer, in Popular Science Monthly*.

ORIGIN OF PETROLEUM.—M. H. Byasson has been led by experiments to give, as a scientific explanation of the formation of petroleum, the following: "If a mixture of vapor of water, carbonic acid and sulphureted hydrogen be made to act upon iron, heated to a white heat in an iron tube, a certain quantity of liquid carburets will be formed. This mixture of carburets is comparable to petroleum. The formation of petroleum can thus be naturally explained by the action of chemical forces. The water of the sea penetrated into the cavities of the terrestrial crust, carrying with it numerous materials, and especially marine limestones. If the subterranean cavity permits these new products to penetrate to a depth where the temperature is sufficiently high, and to come in contact with metallic substances, such as iron or its sulphurets, we have a formation of carburets. These bodies will form part of the gases whose expansive force causes earthquakes, volcanic eruptions, etc. Petroleum is always found in the neighborhood of volcanic regions or along mountain chains. In general it will be modified in its properties by causes acting after its formation, such as partial distillation, etc. Petroleum deposits will always be accompanied by salt water or rock salt. Often, and especially where the deposit is among hard and compact rocks, it will be accompanied with gas, such as hydrogen, sulphureted hydrogen, carbonic acid, etc."

CHEMICALLY OR MECHANICALLY COMBINED.—Prof. Tyndall, in advocating his atomic theory, said that compound substances, such as brass and other alloys are held together by pressure, and could, therefore, be separated by force, and so the atoms are only mechanically combined. Not long ago says the *Cincinnati Artisan* in alluding to this matter, we read of the curious experience of a brass tubing manufacturer which demonstrated the correctness of the mechanical combination. An attempt to produce brass tubing by hydraulic pressure was made, when at a pressure of 4,000 tons on the brass block the copper and zinc separated, the latter forming the tube, leaving the copper behind.

A CURIOUS natural barometer is said to be used by the remnant of the Araucarian race which inhabit the southernmost province of Chili. It consists of the cast off shell of a crab, which, from its curious application, is called the "Barometro Araucano." The dead shell is said to be extremely sensitive to atmospheric changes, remaining quite white in fair (dry) weather, but indicating the approach of a moist atmosphere by the appearance of small red spots, which grow both in number and in size as the moisture in the air increases, until finally, with the actual occurrence of rain, the shell becomes entirely red, and remains so throughout the rainy season.

SCIENTIFIC INVENTIONS.—The inventor is rapidly reaching out into the domain of science in the exercise of his peculiar genius. He has already produced several mechanical devices to act as a substitute for thought and mental labor. The latest which has come under our notice is an instrument called a percentograph, which has been patented by S. J. Tucker, of Richmond, Va., and which is intended to be used for calculating the percentages and amounts of revenue due each road over which freight is shipped. It is claimed for the instrument that it will do the calculation in about one-fifth the time it requires by ordinary clerical work.

SAN FRANCISCO:

Saturday Morning, June 7, 1884.

TABLE OF CONTENTS.

EDITORIALS.—Foreign Patents; Academy of Sciences; The Wheelock Engine, 381. Passing Events; Mechanical Test of Coal; Two Locations in One Application; New Amalgamating Pan, 384. Roasting Copper Ore in Piles; Smoky District; New Dry Ore Separator; Prices of Powder; The Ironmolders' Strike, 385.

ILLUSTRATIONS.—The Wheelock Automatic Cut-Off Engine, 381. Smoky Mine District, Idaho, 385. **MECHANICAL PROGRESS.**—Uses of Aluminum; A New Alloy; Is Puddling Necessary; Testing Steel Rivets; Steel Casts; The Ancients; A Long Straight Edge; Friction; Proportion of Defective Boilers; Solar Heat Machines in Algeria, 383.

SCIENTIFIC PROGRESS.—A Seven Thousand Mile Talk; Dry Sulphuric Acid; Science and Religion; Origin of Petroleum; Chemically or Mechanically Combined; Scientific Inventions, 383.

USEFUL INFORMATION.—What Will Burst a Gun; Effect of Names on Value; Restoration of Faded Photographs; Sawdust in Mortar, 387.

GOOD HEALTH.—Water Poutices; Chronic Alcoholism; Danger in Moldy Bread—Ergot; A Diphtheria; Infected Bells; Increased Duration of Human Life, 387.

MISCELLANEOUS.—Some Researches on the Amalgamation of Gold and Silver, 382. Reader Gulch at Cour d'Alene; The McNair Furnace; Crime in our Towns; Sierra County Quartz; The Harrison Mining Machine, 386. Truman's Process, 387.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 383-89.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 392.

Passing Events.

The attention of the country is just now riveted on the convention in session at Chicago, where the presidential candidate of one of the great parties will be nominated.

There is little news of moment from any of the great mining centers. The great influx of population to the camps in the northwest is naturally resulting in a scattering of prospectors throughout the mineral regions of Idaho and Montana. But those territories show more material advances this year than any other mining sections. Thousands of men have left the older regions for these new ones. Many who went too soon, or unprepared, have returned, and given the country a bad name. Others, however, who have gone, speak highly of the prospects. Of course, in the Cour d'Alene region, as was expected, there will be many disappointed ones who will cry out against the country. But the local papers speak of many discoveries which bid fair to result in rich returns.

COAL.—Dealers report a great falling off in the demand of late. The advent of summer accounts for some of this decline. The consumption for office and household purposes is 50 per cent less at this time of year than in the winter months. But even this does not account in full for the existing depression. Supplies of some coast descriptions are quite large.

SOME San Francisco men are about to begin boring for coal near Verdi, Nevada. They say they are prepared to spend \$40,000 in their search. About twenty years ago a good deal of digging was done at that place for coal, but nothing more was found than the small streak at and near the surface.

A MINERS' MEETING was held this week in Eagle City, Cour d'Alene, for the purpose of establishing a new code of mining laws, especially directed against those holding and not working their claims, and for the adjustment of disputes over claims by arbitration.

Mechanical Test for Coal.

Consumers of coal, whether for manufacturing purposes or domestic use may wish to be able to distinguish and judge correctly of the different classes of coal they are using, particularly if that information can be obtained without much trouble or expense. At the last meeting of the California Academy of Sciences Mr. Melville Attwood, described a simple test he has been using for years. The rough and ready but tolerably correct mode alluded to for determining the different varieties of coal is effected by the aid of a carefully prepared "streak plate," and the method is so simple and easy that the average school boy may make the test. We have one of the plates in the office of the MINING AND SCIENTIFIC PRESS and find it very convenient.

The "streak plate" to be used must be good hard porcelain, which can be obtained in this city of John Taylor & Co., the most convenient size being four inches long by two and one-half wide. As they cannot be purchased ready prepared, to adapt them for testing it is necessary to rub them with a fine emery file, using water with a little washing ammonia in it, till there results a very smooth, hard and even surface on the plate. Then procure good average samples of the coal, letters corresponding to which must be fastened with cement to near the edge of the plate, about five on each side, against which, mark or rub gently a piece of each sample on the plate, which can be easily done by using a piece of cardboard, having slots cut out of it, one inch long by one-quarter of an inch wide. All that is then necessary to roughly determine a sample of coal, is to carefully select a fresh piece, free from decomposition, earthy matter or fibrous "mineral charcoal," and rub it gently on the plate, and then compare it with the streak or marks of the known varieties, by which the character of the coal may be ascertained with tolerable accuracy. To better distinguish the color and lustre of the streak on the plate, it must be turned round in the hand, and the sides moved up and down, so that the rays of light may strike, or be thrown in different directions on the streak.

The different varieties of coal may be classed as follows: 1st class—anhydrous coal, color black, with tinge of brown—blackish brown—containing of permanent water less than 5 per cent, namely: anthracite, black, with luster and slight tinge of brown; bituminous coal, color blackish brown. 2d class—hydrous coal, color brownish, black brown and yellowish brown, containing from 5 to 15 per cent of permanent water, namely: brown coal, lignite, lightish brown, inferior lignite, yellowish brown.

Color of streak.

Graphite.....Black lead
Pumiliaginous anthracite.....Black, leadish black, little luster
Anthracite coal.....Black, with tinge of brown
Bituminous coal.....Brownish black
Brown coal.....Brownish black
Lignite.....Light brown
Inferior lignite.....Yellowish brown

Nearly all the superior varieties of coal are of a blackish color, and contain but a small amount of combined water, whilst the inferior are of a brown or brownish color and contain an excess of combined water.

For the determination of moisture, simple directions are given in "Attwood's Blowpipe Assaying."

"Select from the mass of coal to be examined a few lumps, representing as nearly as possible the average quality. Crush them up in the agate mortar into small pieces about the size of a mustard seed.

"Weigh out five grains, place in a small porcelain dish, and dry at a gentle heat over a spirit lamp. Hard coals sometimes fly when heated, so it is best to cover the dish with a watch-glass whilst heating. After about five minutes remove the assay and weigh; then repeat the heating and again weigh. As soon as they agree the assay is ready."

In Crooke's Metallurgy in the chapter on fuel is found "Examination of different kinds of coal." The nature of coal may frequently be judged of by its external appearance. A full black color, lively luster, and great bardness, indicate a large amount of oxygen, a pitch-like luster shows a small, and a glassy luster a somewhat larger amount of carbon. A black color, strong luster, slight coherence and little tenacity indicate the presence of a large amount of carbon, and also that the amount of hydrogen exceeds that of oxygen. Brownish black color, dull appearance, strong coherence and a certain

hardness indicate a small amount of carbon, whilst the amount of oxygen exceeds that of hydrogen.

Brown coal burns with an unpleasant empyreumatic odor.

The intention of the process of coking is:

1. To concentrate the carbon which the coal contains so that the coke may be capable of producing a higher temperature.

2. To remove the volatile substances which, on burning, especially when used for domestic purposes, have an unpleasant smell.

3. To deprive the coal of the property of becoming pasty at a high temperature in iron blast furnaces, for instance, in consequence of which the blast cannot penetrate sufficiently, and the process of the furnace becomes disordered.

4. To remove part of the sulphur which coal frequently contains in the form of sulphide of iron.

Good coal in coking loses about 30 per cent of its weight and gains that much in bulk.

Some of the inferior coals are valuable from the conditions of the ashes they contain. For instance, in domestic use, if the open grate is filled with some inferior coal, it does not all burn away like good coal would do, but leaves sufficient unconsumed material for some hours in the grate, by which the fire can be renewed without fresh kindling.

Notwithstanding the numerous reports to the contrary, we have not yet received any proof that fields of either good anthracite or good bituminous coal that would yield a good coke, have been found on this coast. The discovery of either kind so situated that the coal would be delivered at a cheap rate on San Francisco bay would supply a serious want.

Two Locations in One Application.

A very important decision has just been made by the Secretary of the Interior in overruling a decision of the Commissioner of the General Land Office. The Gold-Blossom quartz mine at Ophir, Placer county, was located in 1872, after the act of Congress was passed limiting quartz claims to 1,500 feet in length on and along the lode. The owner, Harrison, made application for a United States survey, which was made, including the two locations of 1,500 feet each. The survey was duly approved and advertised, and entry made of the 3,000 feet as one claim. In 1883 the Commissioner of the General Land Office set aside the entry and declared the land embraced in the two locations of 1,500 each to be open to relocation, on the ground that there must be separate application, surveys, etc., for each claim. And, notwithstanding the fact that the necessary entry money had been paid by the locators, the Commissioner decided that the claims were open to relocation the same as if no proceedings had been had. This was because the Commissioner thought that the annual expenditures should be made on each claim, and, this not being done, the claims were open to relocation. The owners supposed that application for patent having been made, there was no further necessity for regular expenditure.

An appeal to the Secretary of the Interior was taken by the owner, but the Commissioner denied the right of appeal, and refused to submit the papers to the Secretary of the Interior on the ground that his decision in the matter was final. Other papers were then prepared here, and Mr. L. L. Robinson submitted them directly to the Secretary of the Interior, without having them pass in the usual way through the Commissioner's office. The Secretary of the Interior then ordered the Commissioner to submit the whole proceedings and papers for review and decision.

The telegraph gives a synopsis of the decision of Secretary Teller in this case, reversing the Commissioner of the General Land Office, as follows: "That when a mineral applicant enters a claim pursuant to the legal requirements, such claim thereupon ceases to be part of the public domain, and is no longer subject to the operation of the laws governing the disposition of public lands; that in such case there is part performance of the contract on the sale, which entitles the entry man to a specific performance of the whole contract, without further action on his part; that the right to a patent once vested is equivalent to a patent issued, and that the proposition that the owner of contiguous locations, who seeks a patent, must present separate applications for each and obtain a separate survey and prove that upon each the required work had been performed, is wholly untenable."

New Amalgamating Pan.

In the ordinary construction of amalgamating pans it is customary to scatter the mercury through the pulp by means of rings or mullers, with shoes of various kinds, between which and dies upon the bottom of the pan the pulp is caused to pass, mercury being placed in the pan to amalgamate any gold which may be found in the pulp. The use of these shoes and dies on any rubbing or grinding surfaces is objectionable because they flour the mercury, and it is very difficult to again concentrate it into a mass and recover all of it from the pulp with which it becomes mixed.

Mr. George H. Malter, of the Etna Iron Works, the well known quartz mill builder of this city, has just patented, through the MINING AND SCIENTIFIC PRESS Patent Agency, an amalgamating pan in which the mercury is kept in one body or mass, and in which it is exposed to the eye all the time during the process, and can be treated with chemicals and kept in the most favorable condition to absorb the metal to be amalgamated.

In this new apparatus there are no mullers or dies, but the inside of the bottom of the pan is smooth, so that the quicksilver can spread over it and remain in one compact mass during the process of amalgamation, and is exposed to the eye in a quicksilver bowl placed outside the pan, communicating by means of a narrow channel or pipe with the inside of the pan.

Mr. Malter employs wooden or small metallic stirrers, which are fixed to the lower ends of the arms so as to just wipe over the surface of the mercury in the pan and keep a bright surface, into contact with which the pulp is constantly brought, so the particles of precious metals may be retained. The arms are vertical, nearly midway between the center and circumference, and at the top bend inward so as to form a sleeve at the center. This sleeve has a hub at the top which is keyed to a vertical shaft passing down through a hollow cone in the center of the pan, and is driven by a bevel gear in the usual manner.

Around the outside of the vertical portion of the arms is fitted a cylindrical band or sleeve of considerable width extending from the feet upon which it rests to or above the tops of the arms. This band is made of a substance to which mercury may be applied, this cylinder being designed not only to regulate the currents of the pulp, but also to collect the amalgam which will readily adhere to it as it revolves with the pulp. The cylinder can also be readily removed and the amalgam be collected from it. This band, from its depth, will prevent the pulp from flowing outward rapidly or directly by centrifugal action; but it will cause it all to flow beneath its lower edge, so as to come into intimate contact with the mercurial surface, which is kept bright by the wipers.

Passing up on the outside it rolls inward into contact with the outside of the amalgamated surface of the board and at the top flows over its upper edge toward the center and down the inside, being thus exposed to constant and repeated contact with a very considerable body of mercury, bright and clean, and the vertical amalgamated sides of the ring, while the mercury is not subdivided is broken up and thus lost.

An important advantage of the amalgamated band traveling in the pulp and in the same direction, is that the amalgam and valuable metal will readily adhere to the surface, and will not be rubbed off by friction, as would occur if the plate were stationary and the pulp formed a current over its surface.

On the outside of the pan is a siphon or cup, which is connected with the lower part or mercury chamber of the pan by a passage through which the mercury may flow and its quality or condition examined from time to time during the process of amalgamation. A discharge pipe leads out from this cup so that the mercury or amalgam may be drawn off at any time. The central cone is narrow at the top, and its diameter gradually increases at the bottom, the shape assisting to direct the pulp beneath the band and keep up the circulation.

THE Carhou Hill mine furnished us with a larger supply of coal last month than any other mine. This mine is owned by the railroad people. Another steamer is being built for the same trade, and both steamers will fail to bring all the coal needed by the railroad people.

Roasting Copper Ores in Piles.

The most approved methods of roasting of sulphide ores or mattes in lump form that are best suited to American conditions are three in number; 1st, roasting in piles; suited to either ore or matte; 2nd, roasting in stalls; suited to either ore or matte; 3rd, roasting in kilns, suited only to ore. Heap roasting has been discussed very fully by both Plattner and Kerl who have left little to add from a theoretical point of view. It is the cheapest method of desulphurizing pyritous ores; and the results of the roasting when properly executed and if the cover of the pile is well stripped off to the point where the cooling influence of the external air has interfered with the process of oxidation, are very satisfactory. It can be employed for ores carrying as low as 15 per cent. sulphur, providing a generous bed of flux has been placed under the pile; and ores containing as low as 8 per cent. can be successfully roasted by using coke fines, bark, or refuse wood with the ore. The principal drawback to heap roasting is the slowness of the process where the value of the copper must be tied up for from one to three months, and the fact that, owing to the great size of the heaps, it must be carried on out of doors, whereby much copper is lost by leaching, or fine dust, and trampling under foot while loading and unloading. A still more serious objection in agricultural districts is the escape of the sulphurous fumes into the atmosphere at so low an elevation and in such a concentrated form that before they can become so diluted with the surrounding air as to be rendered innocuous, they may do immense damage to vegetation, their influence frequently extending for several miles in the direction of the prevailing winds, and being peculiarly fatal to young growing crops.

In calcining tolerably pyritous ores, containing, say, 65 per cent iron pyrites Mr. Edward D. Peters Jr., suggests in a recent government report that a convenient size for the heaps is 20 by 50 feet, and 3 to 5 feet in height. A pile of this size, containing perhaps 250 tons, lighted on the leeward side, well covered with fines, and carefully watched, will burn about 9 weeks and will furnish a product containing from 6 to 10 per cent sulphur. Some weeks before the burning is completed in the very heart of the pile, it can be opened at the ends and two-thirds of its contents removed without seriously interfering with the process. As the whole advantage of heap-roasting lies in its extreme cheapness, every precaution should be taken to save expense in the handling of the ore. It is an excellent arrangement if the ore-car from the mine or dressing-house can be brought on a trestle over a long line of roast heaps, while the track which leads to the furnaces runs parallel to these and on a still lower level. By this arrangement the expenses of roasting can be reduced to a minimum, as the cars from the mine can be dumped directly upon the heaps, requiring only a little spreading into shape, and when the ore is to be carried to the furnaces it can be shoveled or wheeled from the heaps directly into the car, the top of which should be on a level with the ground on which the piles are built.

Smoky District.

The mining districts of Idaho are just now attracting more attention than those of any other region. In continuing our description of them we give this week a map of Smoky District, 25 miles west of Ketchum. The ledges in that region consist of large veins of low grade galena ores carrying from 20 to 50 ounces of silver to the ton and from 30 to 50 per cent of lead. Among the mines are the Carrie Leonard, Silver Star, Salamander, King of the West and Climax. There is a large extent of country in this section of Alturas Co. still to be prospected and it offers a fair field of success. The winters are the chief drawback, but aside from deep snows they are mild and form no serious obstacle to working mines that are properly supplied with necessary material and equipments.

MR. MARSHALL, the original discoverer of gold in California, has presented the Society of California Pioneers with relics from General Sutter's mill at Georgetown, El Dorado county. They consist of the old mill's flutter-wheel, crank-shaft, set of dogs, an iron pike, a hammer, a gudgeon-band, etc. Accepted, with a unanimous vote of thanks.

New Dry Ore Separator.

The latest invention in the line of dry ore washers, or separators, has a frame or casing similar in appearance to that used in an ordinary fanning-mill, and a fan-case located at one end, with an opening through which a blast of air from the fan passes through into the body of the machine.

On top of the casing is a hopper which extends across the full width of the machine and has a slot at the bottom with a sliding gate to regulate the feed. From this feed-opening the sand or gold-bearing material passes between two rollers, one of which has a driving pulley at its outer end and turns in stationary journal-boxes, while the other has its journal-boxes arranged to slide in horizontal guides and has springs behind them so that the roller may move back when large or hard pieces pass between them. These rollers are designed to break up and separate any masses which may be lightly cemented together, so as to liberate particles of gold which may be entangled with them. From these rollers the material is delivered upon a screen or sieve which has a reciprocating and an up and down motion given to it by means of eccentrics. The heavier coarse gravel or material is discharged over the outer or rear end of the sieve, and the finer particles

SMOKY MINING DISTRICT, IDAHO.

fall through upon an inclined amalgamated plate or table, the front end of which is lowered. This plate has channels across it to contain mercury, in which the gold will fall to be amalgamated. The remaining material falls over the front of this plate and through the air-blast from the fan, which blows the finer dust out through the rear end of the machine. The remaining material falls upon an amalgamated plate which slopes slightly downward toward the rear and is given an reciprocating shaking motion by means of eccentrics upon a shaft at its rear end. This plate or table has channels formed across it, and filled with mercury, for the purpose of retaining and amalgamating any gold which may pass while the waste is discharged over the rear end. Both the plates or tables have flanges inclining upward and outward from their sides to prevent the overflow of the material in this direction.

A wind board lies between the upper and lower amalgamating tables, and may be adjusted to give strength and duration to the blast. Above and below the blast, opening from the fan case, are placed direction-boards. The upper one is the broadest, and inclines downward, so that sand falling from the upper amalgamating table upon it will be directed off upon the lower tables. Both these boards are adjustable to alter and control the duration of the air-blast, and are held in place by thumb-screws passing through slots in the sides of the case. This apparatus has just been patented through the MINING AND SCIENTIFIC PRESS Patent Agency, by Herbert Earhart, of Santa Maria, Santa Barbara, who has assigned two-thirds interest to H. D. Livingston and Joseph Kaiser, of this city.

THE British Columbia coal mines sent to this port in May 20,125 tons of coal.

Prices of Powder.

A few weeks ago we stated in the PRESS that the powder companies of this city had been for a long time making no profit on their manufactures because of the low price to which powder had been reduced by close competition. We stated also that shortly the companies would agree on certain prices which they would maintain. Ever since the low prices have ruled for powder, brought about by the competition, no profit of any kind has been earned. On the contrary, heavy losses had to be sustained in many instances. This has resulted in a combination of the different powder companies, and it has been resolved unanimously to raise the prices. Bandmann, Nielsen & Co., general agents of the Giant Powder Co., have issued a circular, from which we take the following, concerning the new rates:

"No. 2, or second-grade powder, 24½ cents free on board here. In car load lots, 1 cent per pound less. Our No 2 powder contains 40 per cent nitro-glycerine. For powder above this strength, add ½ cent for each additional per cent of nitro-glycerine; below 40 per cent, deduct ½ cent for each per cent nitro-glycerine less than 40 per cent."

"The above prices are still very low, but the different companies concluded not to raise the same to that standard which would leave them a reasonable profit, preferring to retain the good

The Iron Moulders' Strike.

The iron moulders employed by the Agricultural Iron Works struck in response to orders issued by the Iron Moulders' Union. The trouble appears to have been caused by the employment in the works of too many boys and non-union men. In a circular which the Iron Moulders' Union sent to all the foundries last July, the union demanded that each foundry should employ no more than one boy for each foundry, and one boy for each eight moulders working therein. Consequently, upon an alleged fracture of this demand by Byron Jackson, the proprietor of the Agricultural Iron Works, the union ordered its men out.

In an interview with a reporter, Mr. Jackson stated that he received a circular from the union last July, but took little notice of it, and on the 15th of last month discharged ten men, retaining only four men and eight boys. Several days later Mr. Jackson received word from the union, informing him that he was employing more boys than the circular which had been sent him in July allowed. Mr. Jackson replied by letter, informing the union that he intended to exercise his right to employ whomsoever he saw fit, and if he chose to give the boys a chance he would do so.

So the situation stands at present. Mr. Jackson, although not willing to state his definite plans, says he hopes to secure non-union men, being willing to make contracts with such by the year and pay the highest wages. The striking moulders, according to the statement of several, are fully determined to make a stand against the practice, as they say, of overstocking their trade by the employment of boys in an excessive number.

The Moulders' Union is also engaged in a lockout with Holbrook, Merrill & Stetson and W. W. Montague & Co., who are joint partners in the Pioneer Stove Works, on Beale street. This was started as an experiment two years ago, and the proprietors intended to give the boys a chance to learn a trade instead of growing up as hoodlums. Everything went smoothly until the union took the matter up, and the result is that the men have left and the proprietors have virtually closed the foundry. The Superintendent, with a few boys, is doing some trifling amount of work. The proprietors state their determination to be independent of all interference from the Moulders' Union.

MECHANICS' FAIR PRIVILEGES.—The Board of Managers of the Mechanics' Fair received the following bids for privileges: By J. E. Sellers, for restaurant, \$156.75; ice cream, \$906.75; popcorn, \$236.75; by George Howell & Co., for popcorn, \$310; by W. Greer, for perfumery, \$100; by Stoddard Bros., for perfumery, \$100; by H. L. St. John, for root beer, \$126; by George Haas, for candy, \$777; by John C. Harshorn, for popcorn, \$257; by G. A. Blank, for candy, \$583.20; by Mrs. A. S. Hart, for ice cream, \$637.50, and for restaurant, \$237.50; by M. Moore, for cider, \$155; by Geo. C. Thompson, for soda, \$827.50; by Justin Gates, for soda, \$800, and for cider, \$230; by D. E. Ciphers, for restaurant, \$305.50; for popcorn, \$307.50; for ice cream, \$876.50, and for candy, \$736.50; by George Spaulding & Co., for printing, \$500. The bids were referred to the Committee of Privileges to report at the next meeting.

At a meeting of the stockholders of the Virginia & Truckee Railroad Company, held at their office in Virginia City, Monday, the following Directors were elected for the ensuing year: D. O. Mills, Wm. Sharon, H. M. Yerington, I. L. Requa, J. W. Eckley, D. L. Bliss, J. E. Wratten, W. H. Blauvelt and H. P. Cohen. At a subsequent meeting of the Board of Directors, the following officers were elected for the ensuing year: D. O. Mills, President and General Superintendent; E. B. Yerington, Secretary; Bank of California, Treasurer; D. A. Bender, General Freight and Passenger agent. The following are the appointed: A. M. Ardery, Master of Transportation; Hume Yerington, General Supply Agent; R. H. Wright, Auditor; George T. Mills, Paymaster; C. C. Atherton, Roadmaster.

ANTI-DRINKS MEETING.—Pursuant to a call of the Supervisors of Yuba and Sutter counties, members of the boards of Colusa, Yolo, San Joaquin, Sutter, Yuba and Sacramento counties met Wednesday, in Sacramento, to devise means to check hydraulic mining. J. F. Flatham of Yuba was Chairman. Mayor Blingham of Marysville spoke and urged upon the different boards the necessity of stopping the flow of sicken forever. He said that whether the valley people assisted or not, Marysville would war with the hydraulic miners until she was victorious. A committee was appointed to decide on the mode of action.

THE United States Mint in San Francisco reports a coinage in May of 91,000 Double Eagles, 300,000 Standard Dollars and 175,000 Hawaiian Dollars. The last named completes the order for \$1,000,000 received a few months ago from the Hawaiian Government. The coinage for May and since July 1, 1883 for account of the United States Government has been \$16,913,500.

THE San Francisco mint has just finished coining \$1,000,000 for the Hawaiian Government.

will and friendship of all consumers. Of course we, like all other powder companies, expect you to obtain better prices. Those given above are the minimum prices at which powder can be sold."

THE Portland Oregonian says: "In digging the well to supply the railroad tanks at Palouse Junction, W. T., the workmen passed through strata of alkali, clay and finely broken basalt rock, to a depth of 185 feet, where water of great purity and limitless quantity was found. The water in the well is five feet deep, and a steam pump actively worked, makes little impression on the quantity. The most curious thing about the well is the fact that in digging the last fifty feet the workmen in the well had to wear heavy clothing and wrap their feet and legs in gunny bags to keep them from freezing, while the men in the open air worked in their shirt sleeves. Water left in the bucket in the well over night would freeze. The water in the well does not freeze because it flows too fast. The new well at Eltopal is seventy-five feet deep, nearly all the distance being through clay. The first twelve feet are through solid white alkali."

THE Helena (M. T.) Independent says: "Miners in the upper district of Mill creek, Gallatin county, say that never in their experience of many years have they seen in that locality such terrible snowslides as have occurred there during the past week or two. The snow lay in great masses on the mountain sides until the late warm weather, and now it comes down in the form of avalanches, carrying everything before it, stripping bare the sides of the mountains and filling the ravines with mingled masses of snow, rock and broken timber."

SUPERINTENDENT McCARDY, of the Paradise Valley Mine, returned from Virginia City, where he had been getting some machinery repaired. Late at night, on his way from Paradise Valley to the mine, he met some of the miners employed in the mine with a team loaded with ore worth \$5,000 per ton. He had five of the miners who are implicated in the theft arrested.

Reeder Gulch at Cœur d'Alene.

The following we take from the Cœur d'Alene Pioneer: The developments made in Reeder gulch have been the talk of the creek. The discovery of extensive veins of quartz along the gulch is a matter of no surprise. It has long been known that some of the best gold-quartz float has come from this vicinity, but it was reserved until the past two weeks to prove that one of the most extensive ore bodies ever discovered exists within the confines of Butte and Reeder gulches. Reeder is a tributary of Pritchard creek from the north, and is 1½ miles north of the town of Murray, and only a few hundred yards east of Butte. It is about a mile long, and forks about ½ mile from its mouth into two prongs, one of which continues northerly and the other north-easterly.

The hillsides and gulches are covered by great quantities of float quartz, and the bed of the main gulch has long been located as placers. The float lays in boulders, many of which are of huge dimensions. The immense boulders of quartz did not attract attention until recently, when it was found to prospect well in gold. Since then the entire country has been located, and it is estimated that the float alone is sufficient to keep a fifty-stamp mill running for two years. The float absolutely covers the whole country between the two forks, and will average from \$20 to \$100 per ton. Some of these boulders would take a miner a month to break up, and on the Claggett lode there is sufficient float above the grass-roots to keep twenty men employed for a month. The discovery of the value of this quartz cannot be over-rated. The following up of this float to several mammoth veins has created an additional furor. A large number of veins have been located, and in every instance the ore shows free gold in more or less quantities. The general course of the ledges is northwest and southeast, with a slight dip to the west. As far as known they lay in a succession of parallel contacts of slate and porphyry. Slate is found on the foot-wall and porphyry on the hanging, and the formation is a desirable one on account of the ease with which it can be worked.

In the main gulch you first come to the Homestake, which was discovered by John King and Florence McCarthy on the 1st of March. It is on the west side of the creek, and crops out on the hillside 15 feet wide for a distance of 50 feet. Only a little surface work has been done on it, but the ore shows gold plainly.

Following up the creek we come to the forks where the Claggett lode is located. John King, Judge Claggett, Richard Lowe and John Flaherty are the owners of this claim. It is within a few hundred feet of the creek and runs in a north-easterly direction. The claim is covered by huge boulders of quartz, which of itself is of great value. The same parties have made an adjoining location called the Friend. It runs up the right hand fork and is likewise covered by huge masses of quartz.

The Golden Gate is above the Claggett lode, and is owned by D. T. Hayes, D. S. Ferguson, Al. Holman, Wyatt Earp, Chas. Foley, Joseph Williams, Jno. Enright, W. Osbourne, Robert Graham and Jobu Cocoran. A shaft is sunk a distance of 30 feet, and the vein holds good for that distance. Assays of an averaged sample returned \$83.09 gold and 60 cents silver per ton. It is one of the most promising lodes yet discovered.

The Poorman and Jenny are parallel veins. The former is east of the Claggett and the latter north. Both show the same variety of ore.

A description of the Kate Burnett has appeared in our columns. It is still one of the best claims on the creek, and the daily developments show up richer and more extensive ore bodies. The ledge is seven feet wide and solid all the way down. It is safe to say that every pound of the ore will pay to mill.

Chas. Copeland has a location below the Kate Burnett called the Golden Chest, on which stand huge cropping and boulders of quartz. There is an immense amount of ore in sight. Little work has been done on it. It is the general belief that the float is from the Kate Burnett lode.

North-east from the Kate Burnett is the Henry Clay, owned by Hawes & Hicks. The ore is the richest yet found in the locality. Large nuggets are met with frequently, and scarcely a piece can be found which does not show gold plainly. It prospects richly in a mortar, and the vein is regular and solid. It runs parallel with the Kate Burnett.

On the left hand fork of Reeder gulch is the Unknown, owned by McCarthy and King. The ledge is four feet in width and nine inches of it has an assay value of \$150 per ton.

Over from the right hand fork of Reeder gulch, a sharp ridge comes down, which divides Reeder from Butte gulch. This hill contains several locations of the same general character as those found between the two forks of Reeder creek. In the Check claim there are three feet of good milling ore opened up, and in the Idahoan, owned by Bryan Rossiter and F. McCarthy, there are several large cuts which intersect the vein in as many places. They all show from 2 to 3 feet of fine ore. The Paymaster was located last year and has a fine body of ore exposed. The vein is a mammoth one, and when it is remembered that it is high grade, its value can be appreciated. Old miners who have visited the Paymaster claim that not less

than 10,000 tons of ore is in sight. It is owned by Patrick Flynn, T. R. Bentley, Robt. Smith and Wm. Curry. The claim is covered by masses of float quartz, and there is enough for a 50-stamp mill to run on if not another pound were mined for two years.

The snow is still about the head of Butte creek, but as far as the line extends float quartz is found. It seems as if the hills between the two creeks were one mountain of gold quartz.

The McNair Furnace.

As there is a movement on foot in this town to organize a company for the establishment of smelting works, using the McNair Furnace, when in Denver last Tuesday we called on Mr. J. K. Hornish, President and General manager of the Vulcan Smelting Mining Company, which made the test of these furnaces at the Miner's Smelting and Reduction Works at Golden. We also met there Edward O'Neill the practical metallurgist, who runs the furnaces. He seemed to be a very careful, practical conservative man and confirmed what he has heretofore certified to in relation to these furnaces.

It is to be borne in mind that the Vulcan Company, running the McNair furnaces, had nothing to do with the "Miner's works" which were closed at Golden. The McNair furnaces were simply given room in the building for the purpose of making their tests, which were claimed to have been in every way successful. But the following is what O'Neill has to say about it:

"We started the first McNair gas furnace, at our works, April 15th and tested it, against the best furnace in our works for thirty days, the charges being equal in weight and quality. The McNair gas furnace saved 58½ tons coal over the Standard furnace, during those thirty days. July 15th we shut the furnace down, for three days, in order to test the saving in the condensing flues, and found it to be at the rate of \$150 per month. July 18th we made another test for twenty-six days, with the following results: saving 64 tons of coal, and doing equal work with the Standard reverberatory furnace. We, now, have been running this furnace for five and a half months, and it has not cost anything for repairs, while the other furnaces cost, on an average \$25 per month for repairs.

"We were so well pleased with the first gas furnace that we built the second; started it August 19th and run it for forty-two days, against all the other furnaces, smelting 115½ tons more ore than any of the other furnaces, and saving 61½ tons coal, over our best Standard reverberatory furnace. The coal used in the gas furnace, was half fine slack, and unfit for use in the other furnaces. The coal used in the Standard furnaces was select lump. The McNair furnaces was easier to handle, and will run longer without repairs, than any furnace that I have ever seen. The furnace has given such good satisfaction at our works, that I think it only a question of time until it is adopted for the treatment of all kinds of ore in Colorado."

The point of most interest to us in Boulder is that our lignite coal, even the nut coal, and slack, can be used for smelting with this furnace, but will not do for the Standard furnace. That's what we've always wanted, to have the coal of the valley, and the ores of the mountains met here in Boulder for reduction.

To make the enterprise a success it is essential that both the people of the town and of the mountains take an interest in the works; that it be in the hands of practical business men, that in addition to the cost of the plant there be a fund for the purchase of one.

At the meeting in this office last Saturday, a committee of citizens was appointed to visit Denver to see Messrs. Hornish and O'Neill, and inquire into this whole business. We hope the result of this spirit of enterprise will be something to build up the town, and to stimulate mining.—Boulder Courier.

NEVADA.—A correspondent of the Virginia Enterprise, in speaking of Nevada as a mining region, says: I wish to say right here that the very existence of this State is dependent upon the extraordinary pluck, energy and grit displayed by just such men as those mentioned, who, in the absence of capital, devote their brawn and intelligence to the development of mines that would otherwise lie idle and unnoticed. In the majority of cases the poor prospector, fighting against discouragements and hard luck, but hanging on with bulldog tenacity in the hopes of eventually striking it rich, is the lever that moves the destinies of Nevada. It is often said that Nevada's agricultural industries are becoming paramount to all others, but every old inhabitant of the "Silver State" knows well that the backbone of this State is in her mineral wealth. Her welfare is more intimately connected with the production of bullion than raising potatoes; of supplying the hard material from which dollars are made than in causing carrots to sprout. Were the mines closed where would be the market for field products? The approbation with which Cassidy's speech on the silver question was received and the avidity with which it was read shows plainly how vital is the subject to us all. Grantsville, Downieville, Ione, Ellsworth and other old camps, once important, languish in desolation and inactivity, awaiting the introduction of the capital that will make them banner producers, and that seem so "backward in coming forward." Still, I firmly believe that there is a happy future in prospect for them.

Crime in Our Towns.

Why is there so much crime, lawlessness, discontent and social disorder in our large towns and cities, is a question that concerns us all. The fact is undeniable. The explanation of the fact is the question. Among the many that may be given we propose to suggest one which is specially applicable to the cities and towns of America. We are inclined to think that this state of things is largely attributable to the confusions and admixture of alien people, with race prejudice, jarring ideas, habits, politics, morals and religion.

Professor Leseley, in his lecture on the "Unity of the Race," says: "Our modern cities are the gravel banks of humanity." We all know what a gravel bank is. Examine one, and it will be found to be a big heap of pebbles, of quartz, of porphyry, gneiss, syenite of nearly all shades of color, white, black, red, green and blue, perhaps infiltrated with dirt and the worst of shales and sandstone. The geologists will tell us that this heap of curious pebbles, cobble stones and sand is not a native production of the place where we find it. That each particle is a stranger and an alien in the land. That once, perhaps a million of years ago, there was an ice deluge that covered half the globe, when there was a winter and a snow-storm which may have lasted for thousands of years stretching all the way to the North Pole. That as this awful winter began to abate, glaciers began slowly and imperceptibly to slide down the mountains, abrading off particles of all sorts of rocks and dumping the whole load at last into one big pile.

In like manner our towns and cities are a huge conglomeration of the disintegrated races of mankind. Here are representatives of the Slavonic race from Suabia, Switzerland, Bohemia, Moravia, Austria and Hungary. Here are representatives of the Teutonic race from Northern Germany and Scandinavia. Here are Celtic people from Ireland, Wales and the northwest of Scotland and the northwest of France, and half-breeds of the same blood, Celtiberians as they are called, from Spain and Italy. Here are the Lowland Scotch and English, a Mongrel people made up of Celtic, Saxon, Norman and Slavic streaks of blood. Here are the black race, first brought to this shore on those pitiless icebergs, the slave ships, and sprinkled into this confused mass are Coolies from China, Malays from Singapore and Kanakas from Hawaii. A babel of languages, race prejudices, alien ideas, traditions, feelings and customs all closely packed and huddled together in the narrow limits of the city. Towns and cities in all ages have been conglomerates of races, but never has this accumulation of alien people been on so large a scale as in the towns and cities of America, growing out of the fact that this country for a century or more has been the chief asylum of the immigrating classes of the whole world, giving to all a cordial welcome. That all this inflow of foreign blood, this vast jumble and hodge-podge of alien ideas, traditions and habits can manage to live together happily and harmoniously, pent up in corporate limits, in the very nature of things is impossible, and we have learned by sad experience that the largest part of our social disquietude, ignorance, pauperism, vice and crime, come from exotic races.

Now, many who seek the hospitality of our land come from a high civilization, are educated, intelligent, thrifty, enterprising, love the land of their adoption, easily affiliate with its political ideas and institutions, and become good citizens. But thousands who crowd the immigrant ships belong to what are called in Europe the lower classes, and are ignorant, superstitious, brutalized by servile labor and abject poverty. They come here to better their condition, and expecting to find a promised land, "flowing with milk and honey," and, on being disappointed, become restless, unhappy, and may be easily led by unscrupulous leaders and demagogues into all sorts of lawless excesses. Many of them import here political doctrines that are in direct antagonism to our institutions, and are promotive of social disorders. Socialism, communism, Jacobinism, Kearnyism and dynamite warfare are all exotic ideas, worse than the Canada thistle to the New England farmer. Out of this caotic and incongruous element came the New York riots, the Molly Maguires in Pennsylvania, Sand Lot rioters of San Francisco, and a majority of the inmates of the hospitals, the asylums and penitentiaries. Out of this medley of races there may emerge some day a new form of civilization—a sort of metamorphic rock in the geology of humanity; but in the meantime we are weltering in the agony of this chaos, and must expect a great deal of trouble before the new order of things comes forth.

THE LARGEST RAILROAD CONTROL.—The London Economist is the authority for the statement that the Pennsylvania Railroad Company controls the largest income of any joint stock company in the world. The greatest English company—the London and Northwestern Railway Company—last year earned a gross \$53,500,000, or, including "controlled undertakings," possibly \$60,000,000, while on the continent the most important line—the Paris, Lyons and Mediterranean—earned a gross \$70,000,000. Such figures are a long way short of the Pennsylvania receipts, which exceeded last year \$100,000,000.

Sierra County Quartz.

The Sierra County Tribune says: The facts fully warrant us in saying that ere another twelve months rolls around Sierra county will have taken the lead above all competitors as the banner mining region of California. In the Sierra City district alone there are at the present time 90 stamps pounding away night and day on good paying ore. To our certain knowledge 80 more stamps will be in operation in that vicinity before snow flies next fall. In this estimate we are not counting two or three other mining enterprises that are more than likely to assume a tangible shape this summer. There are numerous gold-bearing ledges in the district which will surely secure the substantial co-operation of capitalists as soon as their attention can be directed to them. In the southern portion of the county mining affairs have been somewhat under a cloud for the past couple of years. This has resulted from several causes. The Alaska mine, at Pike City, was just getting in a condition to pay handsomely when a fire swept away the shaft works, involving a moneyed loss upon the company of some \$40,000, and the stoppage of work for one year. This was a great misfortune to Pike City, and indeed to the whole county. But now operations have been resumed at that mine, and it will not be long before the pleasant music of the 20-stamp mill will greet the ears of our Pike City friends again. The history of the Golden Gate and Harlen mines, Alleghany, is too well known to require repetition. Suffice it to say that the manner in which those mines were operated proved a great detriment to the mining interest of that section, and served to put a damper upon other enterprises that might have been inaugurated. However, the uncovering of the Rainbow bonanza and the taking out of a couple hundred thousand dollars in a few months' time, bolstered up the condition of things, and convinced outsiders that it only required proper management and a little pay-grit to reap golden treasures from the mineral veins of Old Sierra. The Rainbow Company are now pushing ahead a new tunnel that will give them several hundred feet of stoping ground and insure a big paying mine for years to follow. New enterprises are being talked about over that way, which, when carried out, will add greatly to our mining prosperity. One word more concerning the Sierra City district. The Sierra Buttes mine will in a few months give employment to between 300 and 400 miners. At the Columbo mine there are some 60 men employed, and the resuming of work at the Marguerite mine will insure the employment of a big force there. Altogether, the Tribune is well satisfied that its predictions made in past months are coming true, and that Sierra county will wear the banner.

The Harrison Mining Machine.

Important mining machine experiments have lately been made in the presence of a number of colliery proprietors, Mr. Robson, Assistant Inspector of Mines, and others, at Alloa Colliery. Mr. D. Whitcomb, Chicago, arrived in Scotland a month ago with the view of bringing the Harrison improved mining machine before the notice of colliery proprietors. He obtained permission from Mr. Roxburgh, of the Alloa Coal Company, to test the machine, and, accordingly, he had three introduced into the Whimhall pit. Two were taken to the long wall workings, and one to the stoop-and-room, so that a thorough test might be made in moderately soft and hard coals. The machine is adapted for holing and cutting, or, technically, shearing coal, and is worked by compressed air. It weighs 600 pounds, and is therefore easily removed from one place to another. The machine, when in operation, requires two men in attendance, and strikes from 190 to 210 blows per minute. The operation is exactly similar to that of a vertical bore. The experiments were considered most satisfactory, and in the long wall the machine repeatedly drove a piece of holing six yards in extent in a distance of three feet in twenty minutes, the men in attendance showing less signs of exhaustion than those engaged with the picks. In the stoop-and-room, where the coal is exceedingly hard, the work performed has been remarkable. In a tough fire-clay holing the machine pierced over and over again a hole five feet square in 26 minutes, while the shearing was cut in a distance of four feet in a coal fully as many feet in thickness in 23 minutes. Mr. Whitcomb claims that two men and one of his machines can perform as much labor as eight skilled miners. As to the expense, it appears from the experiments in mines where six machines might be introduced, the wages of three men to each machine would meet all the outlay incurred in every connection—that is to say, that 4s. 6d. per day would meet the expense of the driving power, etc., of each machine. One important feature is the fact that the continual freeing of the wasted air improves considerably the ventilation of the workings. We learn that Mr. Roxburgh has signified his intention of introducing the Harrison machine in every seam practicable, and it is expected that other Fife and Clackmannan coal miners will follow suit.—Iron.

Truman's Process.

From a letter in the *Virginia Enterprise* we make the following extract: Not far from Belmont are large deposits of base ores, so wonderful in extent and rich in noble metals that attention was often directed towards them and attempts made to successfully extract the enormous wealth in gold and silver contained therein. Until quite recently the rebellious character of the ores resisted all efforts to bring their reduction to a practical paying basis. The ore can be found in Tybo and Smoky Valley in unlimited quantities, many of the ledges reaching five to thirty-three feet in width, ascertained from actual measurements taken by the writer. The ore consists mainly of zinc, and is the same generally known in Nevada as Black Jack. One ledge, in the Toiyabe range, was analyzed and proved the mass to be made up of zinc, 33 per cent; gangue or insoluble matter, 30 per cent; lead, 9 per cent; copper, 3 per cent; gold, \$5; silver, \$50. Besides the minerals mentioned there are small quantities of iron, antimony and other substances. Mining men can readily understand how difficult is the successful reduction of such a conglomeration. In the first place it has been almost impossible to roast the zinc in ordinary furnaces without losing a large percentage of silver. Next, the zinc dirties the silver so much that the mercury in the pans cannot attack it, but attaches to the zinc and much silver is lost. The bullion, also, is rendered so base as to be almost worthless.

John B. Truman, an old resident of Nye county and for several months of this town, recently became interested in three extensive deposits, and set about making a series of experiments, which thus far have surpassed his most sanguine expectations. It is probable that his system will shortly bring this county into her old prominence and importance as a bullion producer. Indeed, the entire State may leap into renewed activity and prosperity—"a consummation most devoutly to be wished."

Mr. Truman proposes to first carefully oxidize and chloridize the ores after a method of his own, and then gradually leach the pulp in tanks, through which clear, cold water constantly percolates. Zinc being easily soluble, when well chloridized, passes off with the liquid, leaving the residue in a suitable condition for rapid and thorough amalgamation. By this method the bullion will reach a fineness hitherto unattainable, and all the gold will be saved, gold and silver being insoluble in water. Mr. Truman has applied for patents for his system of tanks and pans, which to say the least is every ingenious. Should the magnificent deposits of Black Jack existing in this county be thus worked, a boom will commence that will echo from the Pacific to the Atlantic. Tybo has untold quantities of this variety of argentiferous mineral that will assay \$60 to the ton in silver, while the Toiyabe range fairly glitters with a similar character of ore. Colorado, New Mexico, Arizona, Idaho, Montana and Utah, and many other States and Territories, besides Nevada, will come to the front in a manner that will astonish the natives. Your correspondent will describe the whole process at greater length and with more accuracy in a future article. For the present, it is sufficient to say that practical millmen hereabouts fully indorse the plan, both as regard the idea of leaching and amalgamating, which is well known, and the peculiar application of the tanks and pans in a manner as novel as it is original.

EFFECT OF THE SAWYER DECISION.—One year ago Brandy city was a prosperous, thriving mining town. The Brandy City mine was then running in full blast and giving employment to some thirty white miners. The future outlook of the town was encouraging. The above company had at that time just got in at a big expense the machinery for running a drain tunnel. That tunnel would have cost a large sum of money and benefited the town accordingly. But now all this is changed. The Brandy City mine has been forced to cease operations. The most valuable gold mine in Sierra county is now lying idle, and a large number of people who were dependent upon its working for support are now left without the means of earning an honest livelihood. The business men and residents of that place are free to confess that the situation is anything but cheering, and many of them are arranging to move away. Judge Sawyer's decision is working terrible hardships to people in the mountains, and with the power that it places in the hands of unscrupulous men there is no telling to what extent it may be used to force blood money from the miner. We honestly believe that such tactics have already been resorted to by men who profess to stand high in the estimation of their fellow citizens. Because the miner is at present the under dog in the fight, it is no sign that he will always remain so, or that he will quietly submit to persecution while in that position.—*Sierra Tribune*.

HERE is the principle adopted by the Lawrence, Kansas, capitalists, who own the Organ smelter, near Las Cruces: "The smelter will not run on Sundays. The fires will be banked up and the furnace kept warm, but no metal will be tapped.

USEFUL INFORMATION.

What Will Burst a Gun.

In bravado a young man placed the muzzle of his fowling piece under the water and fired the charge. The result was the bursting of the barrel near the breech and the mutilation of his hand. Another placed and held the muzzle of his piece square against a piece of plate window glass and fired the charge—powder and bullet. The glass was shattered, so was the gun barrel. Another instance was that of an experimenter who had heard that a candle could be fired from the barrel of a gun through an inch board. He drove a candle into the muzzle of the gun, fired, and the explosion split the barrel almost its entire length, and did not even drive the candle from the muzzle. Still another burst of a gun barrel was caused by the use of wet grass for a wad, well rammed down over a charge of shot. But perhaps one of the most singular exhibitions in this line was a Colt's navy revolver, which some years ago was sent to the factory in Hartford, Conn. This was before the adaptation of these pistols to the metallic cartridges, and it is probable that in loading with open powder and ball only a small amount of powder got into the chamber, and the bullet was not propelled with sufficient force to drive it from the muzzle; at least the bullet did not go out, but lodged. As the shooter did not know whether the bullet escaped or not, he kept on firing until the barrel burst or bulged, and when it was sawed in two longitudinally there were found fourteen bullets wedged one into the other, and so much "upset" by the hammering of the successive explosions of the powder charges that some of them were not less than one inch diameter, being flattened disks instead of conical bullets.

Effect of Names on Value.

Taking arrowroot as an example. To a chemist arrowroot is starch in as pure a form as can be found in nature, and he applies this description to all kinds of arrowroot; but, looking in the "price current" in the *Grocer* of the current week (February 16th), I find under the first item, which is "Arrowroot," the following: "Bermuda, per pound, 1s. to 2s." "St. Vincent and Natal, 2½d. to 3½d.," and this is a fair example of the usual differences of price of this commodity. Nine farthings to ninety-six farthings is a wide range, and should express a wide difference of quality. I have on several occasions, at long intervals apart, obtained samples of the highest priced Bermuda, and even "missionary" arrowroot, supposed to be perfect, brought home by immaculate missionaries themselves, and therefore worth three and sixpence per pound, and have compared this with the twopenny and threepenny "St. Vincent and Natal." I find that the only difference is, that on boiling in a given quantity of water, the Bermuda produces a somewhat stiffer jelly, the which additional tenacity is easily obtainable by using a little more twopenny or I will say fourpenny, to allow a good profit on retailing to the same quantity of water. Putting it commercially, the Natal, as retailed at fourpence per pound, and the Bermuda at its usual retail price of three shillings, I may safely say that nine ounces of Natal, costing twopenny farthing, is equal to eight ounces of Bermuda, costing eighteenpence. Both are starch, and starch is neither more nor less than starch, unless it be that the best Bermuda, at three shillings per pound, is starch, plus humbug.—*Popular Science Monthly*.

RESTORATION OF FADED PHOTOGRAPHS.—It is only to immerse the yellowed print in a dilute solution of bichloride of mercury until all the yellowness disappears. It is then well washed in water to remove the mercurial salt. If the print be a mounted one, it is by no means necessary to unmount it previously to treatment. All that is required in this case is to keep it in intimate contact for a time with blotting paper charged with the bichloride; indeed, this is the plan originally suggested by Mr. Barnes. By the bichloride treatment no lost detail is actually restored, as some have imagined. It is simply that the sickly yellow color which, as it were, buried the delicate half-tints, or what remains of them, is removed, and thus renders the picture bright and clear. Pictures which have been treated with the mercury always possess a much warmer tone than they did originally, as the purple or black tones give way to a reddish brown or reddish purple—more or less bright according, probably, as gold or sulphur had been the principal toning agent. Here a question very naturally arises with regard to the future permanence of pictures which have been thus "restored," seeing that negatives intensified with mercury or transparencies toned with it are so prone to change. In answer to this we may mention that they appear to be permanent—at least that is our experience with some that have been done for many years. There appears to be no further loss of detail, and the whites retain their purity. Indeed, since undergoing the treatment with mercury, no alteration is yet perceptible.—*Br. Jour. of Photo.*

VIENNESE bread is celebrated. It may interest the reader to know something about it. The excellence of the bread is attributed in Vienna to three reasons—the oven, the men and the yeast. I think another may be added, and that is the dry climate. An ounce of yeast and

as much salt is taken for every gallon of milk used for the dough. The yeast is a Viennese specialty, known as "St. Marxer Presshefe," and its composition is a secret. It keeps two days in summer and a little longer in winter. The ovens are heated by wood fires lit inside them during four hours; the ashes are then raked out and the oven is carefully wiped with wisps of damp straw. On the vapor thus generated, as well as that produced by the baking of the dough, lies the whole art of the browning and the success of the "semmel."

CORK BRICKS are a new building material recently introduced into some parts of Europe. The material used in these bricks is a mixture of cork, silica and lime. It is stated to be a perfectly durable material, guaranteed not to rot. It has the advantage of keeping out heat and cold. It is light in weight and easily applied. An interior wall might be built of it where an ordinary brick wall would be too heavy, whilst it would be equally durable and substantial. It is nailed up to laths as a covering under roofs or for ceilings, for wall linings, and for under floors, as it is said to be an admirable preventive of damp, and a sound preventive also. The mode of application of this material is an easy, says an exchange, that, its good qualities being taken for granted, a large use of it must follow. It is stated to be in extensive use in Germany.

SAWDUST IN MORTAR.—Sawdust is said by some one to be better than hair in protecting rough cast from peeling and scaling under the influence of frost and weather. The sawdust should be first dried, and then thoroughly sifted in order to remove the coarser particles. A mixture is then made of two parts sawdust, five parts sharp sand, and one part cement, which should be thoroughly stirred together, and then incorporated with two parts of lime. It is claimed to be cheaper, lighter, warmer, more porous, than ordinary mortar, and by its non-conducting qualities causing the inner surface of the walls to retain the heat which sand plastering allows to escape.

CASTOR OIL is said to be a good lubricator for machinery by reason of its great adhesiveness and elasticity. On this account it is also comparatively cheap; cheaper, in fact, than many of the lubricators, axle greases, etc., offered for sale, which are often, for the sake of increased weight and volume, adulterated with worthless and even deleterious substances.

COTTON SEED HULLS are being substituted for cotton waste for packing journal boxes of railway cars, and are said to effect a saving of fully one-half the cost and to answer a good purpose.

GOOD HEALTH.

Water Poulitices.

A water poultice for the throat may be made as follows: Take four thicknesses of old cotton cloth, three or four inches wide, and long enough to extend from ear to ear. Dip it in water, hot or cold, as the condition of the throat may require. Over these folds of cotton cloth apply a layer of cotton-battening, an inch in thickness, and long and wide enough to cover the cotton cloth. Over this place a strip of waterproof cloth, or oil-silk. Apply to the throat, and keep in place by a bandage.

This poultice, if cold, will induce a local sweating, that will relieve the mucous membrane, or inner lining of the throat. When nearly dry, wring the four folds of cotton cloth again in cold water, and repeat the application for two or four nights, if necessary.

It may be wise to keep children, who are thus treated, within the house for a few days; but if they must go out on the following morning, wash the throat with cold water just before the patient leaves the house.

The water poultice should be cold in all cases in which inflammation may exist, but should be hot if ulceration or suppuration exists. A sore throat needs cold water, but suppuration needs hot—as the diseased throat of diphtheria, or scarlatina in abscesses.

A sponge poultice has some advantages above all others, and is made as follows: Make a flannel bag three inches wide, and as long as any given affection requires. Fill this bag with very small bits of sponge; then soak in hot or cold water, as the case may need. Cover the outside with layers of cotton-battening, and over this some waterproof material. This poultice is elastic, and may be kept constantly near the skin, and will keep the throat at a uniform temperature—a very important point in diphtheria and scarlatina, and all other maladies in which suppuration exists. Cold sponge poultices may be applied in the early stages of scarlatina and diphtheria to lessen the tendency to inflammation.—*Phrenological Journal*.

Chronic Alcoholism.

Two eminent physicians of Paris, Doctors Beaumetz and Andige, of Paris, have been studying the subject of chronic alcoholism during the three years past. All their numerous experiments were conducted on pigs, in order to determine the toxic powers of alcohol. It is thus that these gentlemen have been able to determine what amount of alcohol, proportionate to the weight of the body, suffices

to produce death by the gradual diminution of temperature. The more the alcohol departs from that prepared from wine, that is to say, grapes, the more it is noxious. Thus, the spirits prepared from leas, grain, beet root, potatoes, etc., are dangerous, as they contain greater quantities of deleterious substances. Each pig received over seven ounces of alcohol daily, and every time an animal was given more than a dose of the one-fiftieth part of an ounce per 2½ pounds of its weight, it lost appetite and became affected with drunkard's retchings. Post-mortem examination revealed that the digestive tube was intensely congested, but the liver appeared sound. However, the liver of the pig consists of a fibre of a most resisting nature. All the animals were attacked with lung congestion, due to the elimination of the alcohol by that organ, and the immobility of the animals when "drunk;" thus rendering them very susceptible of cold. It is important to note, great alterations ensue in the arteries, and especially in the aorta. The nervous system of the pig, which is so very different from that of man, was but little influenced by the alcoholic intoxication. Inebriety produced in the pigs stupor and sleep. In man the predominance of brain explains the cerebral effects of intoxication. The same proportions of pure origin alcohol produced relatively little effect; that from grains and roots was slow but certain poison. The doctors explain that a portion of the alcohol, in presence of the globules of blood, becomes changed into acetic acid, the latter unites to alkalies, forming carbonates after having been acetates, and finally disappear in the forms of carbonic acid and water.

Danger in Moldy Bread—Ergot.

A singular case of poisoning from eating a pudding made in part of moldy bread is reported in the *Sanitary Record*. The main facts of the case may be briefly stated as follows: The principal materials of the pudding consisted of scraps of bread left from making toast and sandwiches, and they had been about three weeks accumulating. To these scraps were added milk, eggs, sugar, currants and nutmeg. The whole was baked in a very slow oven, and was subsequently eaten by the cook, the proprietor of the eating house in which it was prepared, the children of the proprietor and two other persons. All of these became violently ill, with symptoms of irritant poisoning. One of the children (aged three years) and one of the adults died. The necropsy of the body of the child caused the medical men to suspect poisoning, and accordingly the viscera, together with the remnant of the pudding, the materials used in making it, the matter vomited, etc., were sent to a chemical analyst, Mr. Alfred Allen, for examination. He made tests for several poisons, but without positive result. A puppy was fed with the pudding for two days without any poisonous effect. He was then led to look for ergot in the pudding, and was soon startled to find unquestionable evidence of its presence, as far as the chemical reactions went, though he was unable, with the aid of the microscope, to detect any actual ergot. From these facts Mr. Allen infers that the reactions heretofore supposed to be peculiar to ergot are common to other poisonous fungi.

A DIPHTHERIA-INFECTED DOLL.—It may be remembered that a good deal of prominence was given last fall in the papers to the occurrence of diphtheria in a family in Amsterdam, New York. Two children died at intervals of several months, and a third was taken sick. The Board of Health appointed a committee to investigate, which examined the house and its surroundings, and obtained a statement from the attending physician. They have recently made their report, finding that there was no bad conditions existing in or about the house sufficient to explain the appearance of the disease, and they concluded that it came from a cat which was fondled by the child that first fell ill. This cat was found at the time to have a swollen throat and to be suffering from a discharge from the mouth and nostrils. It died a few days afterward. Three days after the death of the cat the child fell sick with malignant diphtheria and died in about a week. During its illness it played with a doll, which was afterward given to a younger child, as it was supposed to be properly fumigated with sulphur fumes. This child, shortly after being allowed to play with the doll, also fell ill with the diphtheria and died. The third child also played with the doll and fell ill, but recovered. The Board of Health, therefore, traces the re-appearance of the disease in the family, after the death of the first child, to the doll.—*Sanitary Engineer*.

INCREASED DURATION OF HUMAN LIFE.—Medical and other statisticians, who have given attention to vital statistics, have, after decades of observation, acknowledged that the duration of human life has been prolonged and the period of vigorous activity extended. In consequence of this increase in the expectation of life, corresponding alterations have been made by actuaries in the life insurance tables.

THE British Medical Journals say: "We often hear a great deal about the dampness of our climate as a cause of disease, of the respiratory organs especially, but the death rate and the amount of rainfall do not appear to stand in any definite relationship, whereas a spell of cold weather produces an immediate and notable effect."

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

ZEILE.—Amador *Sentinel*, May 28: Said Alvinza Hayward the other day: Dr. Zeile was very liberal to W. F. Detert in offering him the Zeile mine for \$250,000—that is in agreeing to sell him the property for three or four times its value. Nevertheless we are inclined to the opinion that were Hayward offered the property at the same figures he would jump at the chance. The improvements above ground cost far more than the figure mentioned, and they are comparatively new, and the mine is paying. What better investment would Mr. Hayward desire for his surplus capital. Rock is now being taken out of the Modoc mine, in the Pioneer district, which prospects well, and another big crushing is anticipated. Things are quiet at the St. Julian. The mill is pounding away steadily on rock that is said to be paying expenses, though nothing of an extraordinary nature is reported. Judge Reed has his concentrator there and is confident that it will work satisfactorily. Now that W. A. Nevils has purchased the little ranch, it is said to be the intention of resuming operations on the mine thereon. This would be good news for Jackson, if a fact. Every pick struck between town and the river is an advantage to the place, more so than twice the amount of work expended in any other locality. We have another rich quartz discovery reported this week, one made in a mine owned by Messrs. Bartlett and James and John Petty, at Fort Ann, on Dry creek. From a reliable source we learn that the discovery is likely to rank with the richest ever made in the county. The ledge is two and a half ft. wide, and the softer portions of it are paying from \$1 to \$2.50 per pan. In this neighborhood rich float has been discovered for years, but this is the most extensive discovery ever made there. From this it will be seen that the eastern section of the county is waking up, and is determined to put in her claim for notoriety as a bonanza section.

GOVER.—Amador *Ledger*, May 28: It is now definitely settled that the Gover mine will start up shortly. Messrs. Call and Ashby—both officers of the company—were up lately, looking at the property and making arrangements for resumption. It is also understood that the Amador Canal Co. are identified with the enterprise. Work will be prosecuted through the new shaft, and it is believed that a pretty thorough exploration will be made. John Palmer and J. Wilds went up to the Acme mill last Tuesday, for the purpose of making a test run of rock from that quartz mine, the owners not being satisfied with the result of previous crushings. The South Spring Hill mill is running steadily, with prospects as flattering as ever. The North California Mining Co. have levied an assessment of 4 cents per share. Also changed the principal place of business from Sutter creek to Amador City. The face of the big tunnel at Middle Bar has passed during the week through a large body of quartz. It has not been assayed, but from appearances it is thought to be of paying character. Reports are current that another rich pocket has been struck in the upper tunnel of the Mammoth mine. We have not heard the particulars. The St. Julian mill was brought to a standstill Wednesday last for an indefinite period. The cause of this rather unexpected action is attributed to a lack of pay ore to keep it running. For several weeks past the mill has been running almost exclusively on slate, and experience has proved that this stuff is not so profusely freighted with gold to justify the running of a one-stamp mill at a cost of from \$5 to \$6 per ton in milling expenses. Work is being pushed ahead in the mine. It is intended to open up the mine and separate the pay rock from the rubbish, so that hereafter the mill, when in motion, will be kept at work on quartz that will be likely to yield a fair profit over running expenses. It requires ore that yields from \$8 to \$10 per ton, to leave any margin of profit in working with the present crushing facilities.

El Dorado.

TUNNEL.—Georgetown *Gazette*, May 28: The tunnel started by Gibbs & Hulbert a year ago last January to open up the Bright Hope mine at a depth of 175 feet is now in 236 feet. The tunnel runs southwesterly quartering across the slate, and has about 125 feet more to run before reaching under the 75 foot shaft with which connection will be made.

Inyo.

THE MAXIM MILL.—Inyo *Independent*, May 28: Wm. Hedge informed us yesterday that the mill was crushing away and working smoothly, doing better work than was expected. Mr. Hedge is of the opinion that the ore will pay handsomely. The rock-breaker met with a little accident, but will be ready for work again by to-night.

Mono.

GENERAL NOTES.—Homer Mining *Index*, May 28: Supt. Winterhalter arrived and put a force of men to work clearing the snow from the Gorilla tramway early this week, and it is believed this preliminary work will be completed to-day. Some repairs or alterations are necessary about the running gear of the tramway, but these will consume but two or three days. The Gorilla Company has secured one of Colonel A. E. Redstone's newly patented "Planet" quartz mills, which is expected here tomorrow. The mill is of five-tons capacity, and the experimental test of its efficiency will be made at the Lundy Reduction Works. If it should prove a success, two other mills of a similar kind and capacity will be ordered at once, and the three (with an aggregate capacity of 15 tons per day) will be put up at the foot of the company's tramway. The working force in the May Lundy mine is being increased as fast as supplies for the men can be got up to the boarding house, 16 additional men having been put on during the week. The first team or the tramway started up yesterday morning. The tramway was but slightly damaged by the heavy snows of the past winter, only about 90 ft. of it having been carried away. The mill has been thoroughly overhauled and put in excellent order, and is now running on concentrates. The additional five-stamps are looked for every day, but the mortar will be somewhat delayed. Penters' big teams are expected out on

Monday to begin hauling ore. Jonesburrow has been the scene of much activity during the current week, and as everything is now in readiness, the Virginia Creek Hydraulic Mining Company will turn the water into the giants on Monday. As the gravel fields of this company, lying subjacent to the \$8,000,000 diggings of Old Mono, are known, by the limited operations of last season, to be very rich, and water will be abundant throughout the present season, it is confidently expected that this company's shipments of gold dust will be steady and heavy till winter sets in. The working force in the Bryant mine was largely increased last Monday, it being understood that negotiations for a mill had taken such a favorable turn that success was assured. A large quantity of high grade ore will at once be taken from the 130 level, and held in readiness for the pack trains, which will be put on as soon as the trail down to the Lake canyon toll road is clear. D. E. Jones, of the Virginia creek hydraulic, thinks it quite probable that work will be resumed on the Detroit copper mines in Jordan district in the near future.

RUMORS.—Bodie *Free Press*, June 2: The atmosphere of Bodie is filled with stories of the different shapes in which the spring boom is to strike the camp. It is reported that the Noonday days are to be started up under the management of Wm. Irwin; that the Standard mine and mill are to start up immediately; that the Standard-Bulwer mill is to run to its full capacity on Bodie Con. ore; that the Bodie Tunnel mill is to run on its own ore. The powers that be are endeavoring to so arrange matters that the Standard-Bulwer mill will be put to work on Standard and Bodie ore—15 stamps to be used on each. Those who are familiar with the construction of this splendid mill know that the scheme is practicable, as the parallel batteries deliver the pulp to their respective tanks on opposite sides of the pan-room, and the work from end to end is as completely separate as though done in different mills. This will be a very economical arrangement, as it is well known here that ore can be reduced at less cost in this mill than in any other in the district. If this change goes into effect it will let out the Standard, Bodie-tunnel and Bodie mills. We are assured, however, that the Bodie Tunnel Co. has enough good ore to keep their own mill running, and if the Bodie lease is not renewed they will resume work on their own ore. With the Bulwer-Standard, Bodie Tunnel and Syndicate mills running on good ore, the little mills working on tailings down the canyon, and the almost assured success of Gov. Bladell's enterprise at Del Monte, the outlook for the summer's work is not so very discouraging, even though the Noonday stories should prove unfounded.

BODIE CON.—Upraise No. 1 has gained 6 ft. during the past week; total height, 225 ft. Upraise No. 4, 300-foot level, has gained 7 ft; total height, 75 ft. A drift north from bottom of upraise, which was started on the 28th ultimo, is in 9 ft. A drift south from upraise No. 1, also started on the 28th ultimo, is in 8 ft. There were crushed at the Bodie Con. mill 110 tons of ore, and at the Bodie Tunnel mill, 332 tons. The average assay of the pulp was \$23.51, and of the tailings, \$2.97.

BODIE TUNNEL.—The north drift on vein, 200-foot level, was advanced 19 ft. The vein in the face is 2 ft wide.

Nevada.

RICH STRIKE IN THE CHAMPION MINE.—*Transcript*, June 1: The new shaft on the Champion mining property, commenced about six months ago, has attained a depth of 200 ft. From this point drifts were run north and south. The workmen in the north drift, after running 13 ft, came upon a fine clute of sulphureted ore on Thursday last, which is two ft in thickness and which, those who have seen it and pretend to know say, is rich as any taken from the Nevada City mine. The owners are in high glee over their rich strike, which appears to be permanent, and if so will pay them for the immense outlay involved during the past nine years that they have been prospecting the claim. We trust that it may prove a bonanza, and that the mine may be justly called, as its name predicts, the Champion.

NEW YORK HILL MINE.—*Foot-hill Tiding*, June 3: Some extra good ore is coming from the New York Hill mine, and gives great promise of the mine yielding largely in the near future. Several days since some rock was taken from the No. 10 drift north, and paid \$400 per load, and on Saturday a ledge was blasted open, in the No. 11 drift north, which just glistened with its golden treasure.

ENJOINING HYDRAULIC MINES.—Nevada *Transcript*, June 3: United States Marshal Drew arrived at Dutch Flat Monday and served injunction papers on Phil. Nichols, who owns a small hydraulic claim there, and S. Wheeler, Supt. of the Little York and Liberty Hill claims. The plaintiff in this case is a resident of Germany who owns some land along Bear River above Wheatland, and all the hydraulic mines from Quaker Hill down to Dutch Flat have been included in the complaint. A telephone message received from Chalk Bluff yesterday stated that the Marshal was there on his way to Quaker Hill.

Plumas.

QUARTZ DISCOVERY.—Greenville *Bulletin*, May 28: There has been considerable excitement in town during the past few days concerning a new quartz ledge discovered near the Round valley reservoir. The discovery was made on the 19th inst. and the lucky owners are Joe Rowett, foreman of the Sun Set, now in successful operation, John McIntyre and Sol Johnson. The location lies northwest of the Round valley reservoir dam, and nearly west of the John Ellis claim, which was worked in early days and yielded its owner rich returns. The owners of this new find consider it an extension of that famous lode, and think they have a genuine bonanza. The vein runs nearly east and west, and has been uncovered at intervals for nearly 600 ft, showing a width of from three to ten ft. The quartz prospects the entire length and it is estimated that it will pay \$10 or \$12 per ton. The ore is fragile, of a rosy appearance, and easily removed with pick and shovel. A tunnel is now being run, which will tap the ledge within two weeks at a depth of 55 ft. If at that depth, the quality of the rock proves equal to the croppings, the find will be of great value. The location of the ledge is most excellent for cheap working. With less than 200 ft of tunnel backs of 150 ft may be had. By hauling the rock less than half a mile excellent water may be had just below the dam of the Round valley reservoir. All of the owners are old miners, men who understand the na-

ture of a mine and the value of quartz. It is a ledge that poor men can work. An extension, named the Gore claim, has been located by John McIntyre. It joins the Forest King or the east and the Ellis & Davis claim on the west. It is reported that the Halstead mine is looking better than ever. The ledge is very wide and prospects well all through. It bids fair to be one of the best mines in the State. The Gold Stripe mill will soon be in operation. The Supt. Geo. Standart, is busy getting things ready. By Monday 12 stamps will be running. Work in the Riverdale mine, near Quincy, is progressing finely. Mr. Russell is as busy as ever and looks after things with his usual energy. A. Dragovich has been in this section several days past looking at mining properties. He represents capital looking for investment.

LORING AND LEAVITT'S MINE.—*Plumas National*, May 28: Last Tuesday we dropped in on this mine, and found them hard at work getting their new shaft started, and it was then down about twelve ft. The machinery from the old shaft has been cleaned up and moved to the new location and seems to work smoothly and well. The foundation timbers are large and massive, and everything about the new works seems substantial. A small steam pump is now used when any water troubles the shafters, and as soon as depth is gained its place will be taken by an 8-inch Garrett Gas Pipe pump, which has just arrived from below, and is ready to put in. It is a fine pump, and should do good work. The shaft is 4x7 ft in the clear, and a partition divides it into two compartments—one for the bucket and the other for the pump. It will be heavily timbered, and tightly lined to keep out the water. It is close to 100 ft to headrock. Mr. Wm. Melike, who has full charge of the shaft, is the man for the place, and if he don't put it down rapidly and well, nobody can. Fifteen or twenty men are employed by the company, and the work of sinking goes on day and night. The new shaft is close down to the Riverdale line, and all the Loring & Leavitt ground can be worked from it. The owners are confident that they have several hundred feet of very rich ground, and they are making every arrangement with a view to permanency.

San Bernardino.

CALICO.—*Print*, May 31: The news in Calico is slack this week. Work is progressing quietly on the various mines and developments are being made as usual but nothing of a startling nature is noted. The Escheque has as large a showing of ore as any prospect in the camp and there is every indication of its becoming a good mine. The ore so far is running from \$80 to \$300 per ton. Mr. Brisson one of the owners says that he will commence shipping ore about July 1st but at present does not know to which point until he ascertains where the cheapest milling can be done. The Bismarck is looking well and the work of development going forward as usual. The same may be said of the Humbug. The parties who are chloriding on the Occidental grounds are mostly making money.

BONANZA KING.—The Bonanza King mine of Providence mountain, has paid a \$25,000 dividend for April last. This makes \$75,000 for the last three months. Some of the Los Angeles stockholders feel very comfortable at the way this royal mine is panning out.

Sierra.

A MAMMOTH LEDGE.—*Sierra Tribune*, May 28: The Mammoth quartz ledge is located one-quarter of a mile east of Brandy City and is owned by John J. Williams. The ledge is probably the most extensive in the country, averaging about 250 ft in width. Assays of the ore give good returns in gold. It also contains silver, nickel and copper. Mr. Williams had about completed arrangements with a party of eastern capitalists to develop his property in lieu of a one-half interest in it, when, owing to disastrous investments elsewhere, much to their regret, were compelled to abandon the project. It is the intention of the owner to go ahead and open up the mine as rapidly as his means will permit of. The mine is so situated that sufficient water to run any number of stamps can readily be obtained from Cherokee creek.

THE JIM CROW QUARTZ MINE.—The above named quartz mine is located one mile and a quarter above the mouth of the Jim Crow canyon. R. D. Williams, one of the owners, was down from there Sunday and informed a *Tribune* reporter that the Company proposed to drive work at the mine this summer. The vein is between five and six ft in width on the surface and the ore taken therefrom yielded handsomely. A tunnel has been run into the hill 240 ft and it will be run ahead until it taps the ledge. More work is being carried on in this quiet way among the quartz ledges throughout the county than most people have any idea of.

HARD ROCK.—J. T. Mason and Cap. Wilburn were down from the Red Oak claim last week. They report about eight ft of snow at that place. The tunnel is in 240 ft. The rock is very hard at present, and costs something over \$24 per foot to get through it. Indications are very favorable for striking softer rock soon.

GOLD LAKE.—*Mountain-Messenger*, May 31: Dick Wade came down from Gold Lake Thursday, on snowshoes to Gold Lake, and thence afoot to Downville. He reports Philo Haven with two men busy washing at his diggings. L. Foss' flume is filled with frozen snow which thus far it has been impossible to clear out. The Four Hill Quartz Mining Co. are using water from their tunnel. D. Steilman is at his mine, three and one-half miles from the Lake, and will continue work this year at his claim. John McDonald was over from Ballarat claim, last week. The tunnel is in top gravel and they are expecting the bedrock to come up as they go ahead. The top gravel prospects.

Siskiyou.

EMPIRE.—*Yreka Union*, May 31: At the Empire mine they have been taking out rock for some six weeks past, but it is only until recently that they struck ore which would pay. They are now running on a good, fair ledge, and the rock prospects very fairly.

Trinity.

LUCKY PICK UP.—*Trinity Journal*, May 30: In coming to town the other day, J. Kellogg of Hay Fork espied what he thought to be a piece of gold in the red dirt by the roadside, near the summit of the Brown's creek mountain. His traveling companion pronounced it a leaf, but Jack was not satisfied with this judgement and on dismounting picked

up a pretty nugget weighing \$23.75. When pieces of this kind are found in the soil on the top of our mountain ranges, who shall say that Trinity has not thousands of acres of auriferous earth which has not yet been prospected? We opine more gold exists where Mr. Kellogg found this piece.

NEVADA.

Washoe District.

ALTA.—*Enterprise*, May 31: Drifting west, along the diamond drill hole, on the 2150 level. The rock is pretty hard, but very good headway is making in the drift. It is now out beyond the wet streak in which the diamond was started; there will be no trouble with water, as none was found by the drill. The diamond drill has been set up at the face of the east drift on the 2150 level.

BEST AND BELCHER.—The east crosscut on the 1200 level, 125 ft south of the Con. Virginia line, is showing quartz of a favorable character, though it carries but little metal as yet. On the 2700 level work has been discontinued, owing to a flow of water that causes intense heat, and the men have been brought up to the 2500 level and put to work at running a northwest drift at that point in a section of unexplored ground.

HALE AND NORCROSS.—Have begun shipping ore from the 200 level to the Mexican mill on the Carson river, where a crushing of 1,000 tons will presently be made. On the 2800 level are easing timbers at and about the station. No work is being done on this level at the points where ore was found.

BELCHER.—The miners have been laid off for a few days on account of the flood in the Carson river causing sufficient back water to interfere with the working of the wheels of the water mills. However, the water has receded, and the men were to resume work in the lower levels last evening.

IMPERIAL.—The lateral drift is in Alpha ground. It has encountered a great deal of quartz, but this has as yet yielded no assays of much value. As this quartz is of a very favorable character, it is hoped that it will somewhere be found to carry ore.

CALIFORNIA.—The usual progress is making in the east drift on the 2900 level. The repairs to the C. and C. joint shaft are still continued. The ground passed through is a mixture of quartz, clay and porphyry.

YELLOW JACKET.—The boilers from the works at the new shaft have been brought to the works at Gold Hill, and are being set up in place of the old ones. Pending this change the miners have been laid off.

UNION CON.—Are drifting in east crosscut No. 4. There is some water in the drift, but not sufficient to prevent going forward with it. The ground is a mixture of clay, quartz and porphyry.

CON. VIRGINIA.—The east drift on the 2900 level has been extended about 30 ft. Are still repairing the C. and C. joint shaft. The material encountered in the drift is the usual vein porphyry.

SIERRA NEVADA.—The north drift on the 3100 level has passed through the dyke or crosscourse of porphyry, and is now in vein porphyry, the appearance of which improves as the drift is advanced.

OPHIR.—Are still finding some low grade ore in the filling of the old drifts and other openings on the 250 level. The ore extracted is being worked at the Morgan mill on the Carson river.

UTAH.—The south drift on the 1950 level has been advanced about 35 ft this week, and has improved in appearance, more quartz being found than heretofore.

MEXICAN.—The winze on the 3100 level was yesterday within 15 ft of the 3200 level. The bottom shows porphyry, clay and quartz.

COMBINATION SHAFT.—Are making good headway in cutting out the bob-station at the 2900 level and in making the other necessary openings.

ANDES.—Some low grade ore is being extracted and a good deal of work done in the way of exploring and prospecting.

UNION SHAFT.—Are repairing the drain drift on the 1600 level. This drift leads out to the north branch of the Suto tunnel.

GOULD AND CURRY.—Two east crosscuts are being run on the 1200 level, in ground that promises well.

CROWN POINT.—What is said about operations in the Belcher is equally applicable to this mine.

SAVAGE.—The bulkhead in the north drift on the 2600 level will be finished by next Monday.

SCORPION.—The west drift on the 500 level is still in vein material of a favorable character.

CHOLLAR.—Are preparing to place a stone bulkhead in the drift on the 2600 level.

Bristol District.

BULLION.—*Pioche Record*, May 28: The output of bullion from the furnace during the week has averaged 80 bars per twenty-four hours. This must be highly satisfactory to the Day Company. The screenings being hoisted from the Gold Ledge mine contain a large quantity of big chunks of rich ore. We noticed that the ore is of high grade, such as was taken out in early days. In those days the miners were not particular and they would scatter good ore in all directions. It will come in good now though. If the men had only been aware of it, they could have made big money chloriding in the screenings east side.

Bromide District.

THE MINES.—*Cor. Calico Print*, May 31: This district is in Nye Co., Nevada. The mines upon which we have been for the past three months at work are situated in a low detached range of mountains a short distance east of the Death Valley or Grape Vine range of mountains and about 25 miles easterly from W. T. Coleman & Co.'s Borax Works at Furnace Creek in Death Valley, and are laid down on Wheeler's maps as the Bald mountains, and by the recent road about 150 miles northeast of Daggett on the S. P. R. R., and about the same distance southeast of the southern terminus of the Carson & Colorado narrow gauge railroad at Owens lake. Both of the railroads are accessible by wagon roads as good as are common in this southern country. The mineral is found in a soft formation of white or marble lime, easily mined, extending northerly and southerly about fifteen miles; the country rock on

the east side of this lime belt is quartzite, and on the west slate, and at many places throughout the entire distance rich silver bearing rock has been found, but as yet little work has been done, in fact none of consequence, except that done lately by our party, and upon the claims owned by Wm. L. Stockton; but for what has been done I will venture the assertion that no better showing can be made in any mining country, both as to quality and quantity of ore. A brief description of the U. S. mine, of which our company are the owners, and upon which most of our development has been done, and which will describe the general characteristics of the whole, will give your readers a fair idea of the merits of the country. This ledge upon which we are now down about 40 ft, although through some considerably rich float rock, was entered at the surface by two crevices, respectively four and seven inches in width, the one on the hanging wall being the largest. For fifteen ft the ledge was badly broken but constantly growing in strength, a perfect foot-wall having been found from the surface, with hanging wall somewhat broken, but at this fifteen ft depth the vein matter became more solid, carrying mineral the whole width of nine ft, the distance between the two walls, the ledge pitching at an angle of about 60 degrees, which it has maintained to its present depth, the ore assaying from 60 to 200 ounces silver per ton, and steadily increasing in amount of rich ore, more black metal, chlorides, and some green horn silver being obtained. In the adjoining vicinity we have seven locations, all showing the same general surface characteristics as this one I have described. About three miles to the north and on the same belt and with the same rich mineral surface indications, Mr. Stockton has the Lady Ellen and two other promising locations upon which work of development with exceedingly flattering prospects is now being done. All of these mines are easy of access, being close to the valley. No expensive roads to build, being at an altitude of about 3,500 ft above sea level. No snow and no exceedingly hot weather, they can be worked throughout the whole year. Water can be obtained in large quantities by sinking in the bed of the Armarosa river which is but a short distance from the mines, or can be piped from the many springs which form the head of the river, while plenty of nut pine wood is just across the valley in the Grape Vine range. There are many other good mines here, and a splendid field for prospecting.

Columbus District.

MOUNT DIABLO.—*True fissure*, May 31: The west intermediate from winze No. 5 is in 32 ft and the ground looks more favorable for ore. The upraise from the east drift from the same winze shows some \$70 ore. Winze No. 6 is down 100 ft, the east drift from the north crosscut, on the third level, shows a few inches of \$80 ore, and this drift is now 60 ft long. The intermediate, between the second and third levels and west of the shaft, is in 33 ft and shows a strong ledge of \$25 ore. The south crosscut from the east drift on the second level has been stopped, after reaching a length of 233 ft, and a raise has been started from the same to connect with the east drift on the first level. The east drift on the second level shows some 15 inches of \$90 ore. The north crosscut from the west drift on the first level is in 43 ft. A small amount of \$50 ore is being taken from the upraise from the east drift on the first level. The sinking of the incline has been stopped for the present, and timbers are being put in from the third to the fourth level, and an excavation is being made for a chute on the fourth level.

COLUMBUS CON.—*Crosscut No. 3*, from the main drift on the 150 level, was extended four ft during the week, and is now about 48 ft in length. The ground is gradually changing from a hard formation to that of an easy working one. The upraise on the streak of ore encountered in the south crosscut from the same level is now up a distance of 25 ft and is about 15 ft in width at the top. The width of the ore vein is about two and a half ft, and gives assay ranging from \$35 to \$60 per ton. The ore is black manganese in character and is deceptive. It is difficult to arrive at the average of its assay value per ton. All the other levels in the mine are now ready for further prospecting, which will be resumed in a short time. At present no work is being done except on the level mentioned.

Esmeralda District.

MILL.—*Bodie Free Press*, June 3: Ex-Governor Bladell, of Nevada, came in from Del Monte station this morning. He says the 20-stamp mill will be ready to start up on full work by Monday or Tuesday certain. The Governor speaks with much hopefulness of the prospects of the old camp and the success of the present run. The mill is in splendid order.

Tuscarora District.

GOLD PROSPECTS.—*Times-Review*, June 28: Within the last few days, Joseph Miller and George Phillips have been prospecting at the head of Eureka Gulch. On Thursday they run a little cut in the side of the hill and struck some rich decomposed quartz which shows to the naked eye a considerable quantity of free gold. The extent or value of the find cannot be even conjectured at present, as sufficient work has not been done to develop the size of the body or vein, or in fact whether it is a ledge or not. It is admitted, however, by all who have visited the place that it is a most encouraging prospect. Several shovelfuls of the decomposed quartz which were panned out yesterday, averaged ten cents to the shovelful. The prospectors ascertained after they had made the location that it was on the "Accidental" location, owned by the Beard brothers and George J. Smith. Arrangements will, however, doubtless be made whereby the discoverers will have an equal share with the locators in the claim. A thorough prospecting of the quartz body will be commenced in a few days.

ARIZONA.

THE BLACK HILLS.—*Miner*, May 23: From Governor Tritle who returned yesterday from the United Verde Copper mines, at Jerome, we to-day learned that the company's furnaces are again running, and turning out a steady stream of high grade silver bullion. The difficulty in obtaining coke has been entirely overcome by the construction of a new road, and at present there is in the vicinity of Sander's station alone, 150 tons, an amount sufficient to run the smelter a week. On the morning the Governor left Jerome ore was discovered in a drift

leading from the Hampton shaft, —150 ft in depth,—toward the Eureka mine. This ensures the 300 ft of ore from the drift to the surface where were found the outcroppings of Eureka ore. There were also found a few ft above the level of the old, another large and unexpected body of high-grade silver ore. On the return trip from the mine, the Governor in company with President McDonald, Dr. Unsell and Wm. Adams, Jr., all large owners in the Company, examined the road from Baker's ranch to the Pines,—the road proposed for a station for the Black Hills, on the contemplated Central Arizona Railway. The party found that the proposed-railroad would reduce the freighting by teams to fifteen miles.

PRESCOTT MINES.—*Courier*, May 28: Just now we can boast of the Hosoris, the United Verde, the Lane, the Silver Belt, the Chicago, of Groom creek, Jack Lawler's mine, In Agua Fria, the Chase group, the Kimball, the Holmes, the Pine Spring, mines in Humburg and Bradshaw Basin districts, besides eight or ten other properties, scattered throughout the country all of which are in condition to yield plenty of precious metals. Mr. Clark, Superintendent of the Chicago mill and mine has received returns from concentrations shipped for him to Pueblo, by the First National bank of Prescott, and is satisfied with the yield, which was about one hundred dollars per ton, over and above all expenses. He is now pumping water out of Chicago mine, and will start mill in about a week.

THE BENSON SMELTER.—*Star*, May 28: Few people, other than those directly interested are aware of the immense importance of the Benson smelter as a developer of the mineral resources of this territory. In its interest mines are worked and ore shipped from all sections of the country. Even far off Mohave sends its contributions, the ore from that section being shipped by way of Kingman, across the Colorado at the Needles, then around by Mohave and the Southern Pacific to Benson. The company receive on an average about five car loads of ore, coke and flux daily, and produce about 75 tons of bullion of an average value of \$500 per ton. Considerable ore is also received and worked from Sonora, most of the shippers from that country send rich rock. The company own and work several mines in the neighborhood of Harshaw. They employ, all told, about 200 men, own most of the teams in their employ. It is reported that they propose shortly to put up a stack for the exclusive working of copper ores.

COLORADO.

NEW TRAMWAY.—*Colorado Miner*, May 28: The new tramway from the Pay Rock mine to the mill has been successfully started up. The Pay Rock tramway, finished and worked for the first time last Monday, is the Huson patent, endless, wire-rope tram, and travels over grooved wheels secured to the cross-arms of elevated supports. The buckets used for carrying the ore are fastened firmly to wire rope by means of clamps, and attached to wire rods. There are forty-two of these buckets on the Pay Rock tram, and carry about 150 pounds of ore each. The Pay Rock mine is a bonanza—systematically, economically worked. Its miles of drifts, cross-cuts, shafts and stopes have produced their hundreds of thousands of dollars, and are still energetically worked with paying results. The crevice in the Pay Rock must be over 100 ft wide. The new strike recently made in No. 3 tunnel level is still producing fine ore, and increasing in size. The width of the streak is now over eight inches, and will run 800 ounces per ton. Hundreds of tons of concentrating ore are being taken from the dumps and will be sent to the mill as fast as the tram can move it. In the breast of the main drift, over 900 ft from the surface, the pay streak of concentrating stuff is over three ft wide. The mill, known as the Pay Rock concentrator, is situated on the north bank of the creek at the foot of Republican mountain, and a short distance this side of Silver Plume.

IDAHO.

OUNCE DIGGINGS IN ALDER GULCH.—*Cour d'Alene Pioneer*, May 24: Of all the many side gulches of Pritchard creek that have won fame for the Cour d'Alenes, Alder, like its historical namesake, is in the van. The developments during the past two weeks bring this gulch to the foremost rank among the gold producers and leaves no doubt that it is one of the richest little gulches that has ever been trod by the patient gold-hunter. The character of the wash is distinctively gold-bearing, and the prospects in every instance justify its claim as the banner side gulch of the camp. Alder creek debouches into Pritchard from the north, at the west end of the town of Murray. It is less than a claim wide, three and a half miles long, and is thickly timbered for its entire length. About one-quarter mile from its mouth it forks into two branches, and on the main creek, and these forks ten acre claims have been staked which cover the entire bottom. During the average season the creek carries 700 miners' inches of water, which with proper handling is sufficient to work every claim the entire season. Its sources are in the everlasting snows of Bitter Root range, and the fall is ample for 12 ft boxes and convenient for full tailed races.

MAIN CREEK.—On the main creek, W. L. James, James Travis, Dennis Rodner, John Doctor and Charles Cottle own No. 1, the Heart mining claim. It adjoins the Ives' claim on Pritchard gulch, and occupies a portion of the Murray townsite. On the Heart claim a drain is walled and timbered for a distance of 250 ft, at the end of which a drift extends 50 ft. Twenty ft of gravel is over this drift and it prospects throughout. Streaks of clay peatmate the gravel in many places, and gold is found deposited in them in coarse colors. The drain is but a short distance from bedrock, and before our next issue sluices will be running on this claim. No. 2 has lately passed into the control of Alexander Christian & Co., who hold deeds in escrow for four-fifths of the property. Considerable work has been done on this claim, an open drain being run 300 ft and 18 ft in the ground. A blind drain has been begun on No. 1, which is calculated to tap bedrock at the lower end of the claim. It is in 100 ft. No. 3 is owned by Baker, Scott & Co., who have been steadily at work for the past two months opening up the gravel. Six men are at work on the claim, and an open drain has been run 300 ft and 30 ft drifted in the gravel. No 4 has seven men at work running a large open drain, 10 ft wide. It will give a good

opportunity to prospect the bedrock, an area of 100 300 ft being exposed at one time. The gravel prospects well.

RIGHT-HAND FORK.—The northeast fork runs around a butte which closely divides the waters of Alder from those of Gold Run. On No. 1 a great amount of work has been done. The firm of Campbell, Pease & Co., and Messrs. Chew, Dugan & Holman are the owners. Three hundred ft of a drain is run, and one set of sluices is running. Six men are at work, who take out daily from the bedrock three to five ounces. When bedrock is reached by the main drain, the output will average over an ounce per ton to the man. No. 2 is being worked by John McClair & Co. They are on bedrock with the drain, and have a long string of sluices running. Six men are working on the bedrock, and on no one day has their clean-up been less than seven ounces of dust. No. 3 is owned by C. H. Hough, P. R. Haysington and R. Pruet. They are running one string of boxes, and their daily runs are open to inspection. It is over an ounce per day to the man, and the gold will average coarser than any yet found in the country. In their last clean-up, but few pieces weighed less than 10 cents, while most of it were nuggets from 50 cents to \$5. They have a bedrock drain 175 ft long. Last Thursday a streak of blue gravel was struck on this claim, which has produced quite a commotion along the creek. It has the appearance of marl, and is absolutely the richest pay streak yet found. It lays on the bedrock, and is ten inches thick. This streak is composed of fine tight gravel, which is held in a blue clay matrix, and is peculiarly adapted to sifting fine gold. It is, accordingly, found to contain fine particles of the metal, which is plentifully distributed throughout the gravel. The claims above and below are on to the strike, as it doubtless runs on their ground. On the northwest fork a great deal of development work is going on which will be appreciated when the sluices are running. The ground here prospects fully as well as the other fork, and the bedrock, when it is finally reached, will show prospects equally rich. Messrs. Hall & Co. have transferred a hill-claim between Nugget and Buckskin gulches to Eastern parties for \$6,000. The hydraulic is running again, and the ditch from Alder creek completed. It is the longest ditch yet constructed in the country, measuring in its windings 2½ miles. It carries at present 300 miners' inches of water, and is capable of running 500 inches. The hydraulic now has a 75-foot fall, with a 1½ inch nozzle. Twenty four men are at work, and the output will no doubt revive the interest felt in the pioneer side gulch of the camp. The first clean-up will be made to-morrow.

DEEP GRAVEL.—The *Pioneer* in its first issue called attention to the fact that one of the greatest gold-bearing gravel deposits ever discovered could be found on the north side of Pritchard creek, and the developments of the past week shows that this deposit is astonishingly rich. Gold is found throughout the gravel and pan prospects vary from 50 cents to \$3.00. The deposit varies from 10 to 150 ft in depth, and at Butte has a bed-rock on the high rim-rock of the present creek. The gold is of a solid rusty cast and has every evidence of being an ancient deposit. The river evidently occupies an extensive bed, and its course was doubtless opposite to the present flow of Pritchard creek. It is quite likely that at one time its waters ran through the pass on the Thompson trail and emptied into the Clark's fork of the Columbia river.

RAVEN CITY.—New discoveries of quartz are being made every day. The snow is rapidly disappearing and the claims are getting into shape for the season's run. Cement gulch, the knowing ones claim, will be the banner dust-producer of the camp. The bed-rock has not yet been reached, but the top layer of conglomerate prospects very richly. Bear and Granite gulches are producing their quotas of dust. The output is steadily increasing. Several large nuggets from these gulches were exhibited in town during the past week. An immense galena lode was discovered just as we go to press, which both in magnitude and richness outranks anything hitherto found. The "Houdan" ledge, discovered a short time ago on Vendetta creek by H. S. Bach, is pronounced by experts as good as the Mother lode.

THE NARROW GAUGE GROUP.—It will be remembered that last winter the Narrow Gauge concentrating works were covered by a snowslide, but it was impossible, owing to the snow, to ascertain the damage. The snow has now disappeared or been removed, and the damage is not as great as was at first anticipated. A few days' work will suffice to place them in good repair, and with good roads the works can be started up again within two weeks, and the shipments of ore resumed. An attempt was made to get a first load of ore through to Deer creek a few days ago, but it had to be abandoned, as the snow in the gulch was still too deep.

MONTANA.

BOULDER DISTRICT.—*Cor. New Northwest*, June 28: Mr. Thomas Conch, representing the Princeton Mining Co., commenced operations here on the 8th inst., with a force of men on the Princeton and Saranac mines. Owing to a rush of water in the main shaft at the Princeton, Mr. Couch has put most of his miners on the east and west ends of the Princeton. In the east shaft a drift is being run along the vein at about 40 ft from the surface. Sinking is progressing on the shaft west of the main. Saranac is situated south of the Princeton. Sinking on the Saranac is the order of the day, with two shifts on. I saw some very fine ore dumped from the bucket at this mine yesterday. Messrs. Cunningham and Gallagher are owners of the Morse mine, an extension of the Saranac. They are also developing this property. All that can be said with a certainty concerning the Princeton mine and the leads in this mining district, is that the work thus far done warrants the belief that the ore deposit here is a large one. There are now between 60 and 75 men in this camp. In the town considerable improvement is going on in the way of building, clearing lots, etc.

PHILLIPSBURG.—*Cor. New Northwest*, May 28: Supt. Perkins of the Hope and Granite Mining companies, is still absent and nothing is known as to the intentions of the directors of the last named corporation regarding the construction of a milling plant here during the coming summer. The Hope mill, with new batteries and tanks, machinery thoroughly overhauled and refitted, will start up

within the next two weeks on a long and steady run. Capt. Plaisted has placed in this mill the finest battery ever constructed in Montana. Rumor hath it that J. K. Pardee, of the Algonquin Company, has received instructions from Philadelphia to pump out the Algonquin mine. Hoisting machinery for the Princeton mine is being unloaded at the shaft. I think a large amount of work will be done on this property during the summer and fall.

NEW MEXICO.

NOTES.—*Cor. Lake Valley Herald*, May 20: The Kingston smelter will "blow in" again in a few days. Dry washers are now being used with good success in the Hillsboro placers. There is some prospect that work will be commenced again on the mines at Shakespear and Leitendorf very soon. The iron mines near Santa Rita are shipping about fourteen carloads of ore every week. The ore is used for flux by the Deming and Benson smelters. The Sundown mine, in the extreme southwestern part of Grant county, about 125 miles from this city, has been bonded for \$40,000 to Lake Valley parties. A shipment of ore was recently made by John Moore from the Pennsylvania, adjoining the Carlisle mine in Steele Rock district, which gave a return of \$136 per ton. W. P. Linder has purchased a one-fourth interest in the New Year's Gift mine, in Gold Gulch. He is a forty-niner, and understands gold mining thoroughly. He will leave for the East in a few days for the purpose of organizing a company with sufficient capital to put in the necessary machinery to work the property on an extensive scale.

CLIFTON.—From what I had heard of Clifton, I thought it would be a good point for prospectors and fortune hunters, and a pleasant place to make a home, but upon arrival there I was greatly disappointed. The place had been greatly overrated to me. There is considerable work going on at the present time, but I was never in a place where one is compelled to put up with so many inconveniences. For instance, wages are not so good as in the average Grant county camp, running from \$1 to \$3 per day. Board costs \$7 per week, with no choice of boarding houses, as there is but one at each mine, and the mines are about eight miles from town. The men are crowded together, nor can they do any better by batching, for it is a burning, blistering country, wood costing \$8 per cord and water \$2 per barrel, so I was told by men living there. The water has to be hauled twelve miles to the mines. The Longfellow is eight miles from the river which is the nearest water. The mines are on the very peaks of the highest mountains, which are one continual series of bluffs, chasms and precipices, the formation being porphyry, quartzite and limestone, underlaid with feldspathic micaceous granite.

ORGAN.—*Rio Grande Republican*, May 31: The smelter blows in again to-morrow on Memphis ore. U. G. Johnson has struck finer ore than ever on the Silver Star. Capt. Crouch is hauling ore from the Stephenson mine to the smelter. There are 47 tons now in the yard. The Girard has over 30 tons on the dump, which will be hauled in at once, and more will be taken out as work progresses. The Crescent City has 40 tons of ore at the smelter, 33 tons more at the base of Little Buck mountain, and new ore will be taken out at once. Col. J. S. Crawford has gone to Pueblo with several carloads of Silver Gem ore. The average returns of shipments from this mine are from \$100 to \$225 per ton. The smelter, which has been at a standstill for a few days since the fall of the flooring, will start up again to-day or to-morrow. Forty tons of ore a day is about the average consumption. Meadows is getting out large quantities of iron ore from the Merrimac, some of which carries silver, and some runs well in gold. It is also needed at the smelter for flux, and will be brought in soon. A great deal of native copper is being taken from the Memphis, and is so common in the output of that mine as to attract no notice. A wheelbarrowful passed us as we were examining the dump yesterday, from which we grabbed a small but fine specimen. Work will now go on in many different properties on both sides of the range. Claims which have mineral that can be treated at a profit at the Organ smelter will be developed. Many others will change hands, for so far all our good prospects have improved under the work done on them. Only last week Mr. Hamton sold a sixth interest in the Birthday, after having done some work for which he was well paid, for more than the whole mine would have brought before the work was done on it.

UTAH.

ONTARIO.—*Southern Utah Times*, May 28: Great interest is being taken in the opening of the new 900 level on the Ontario. If it shall prove as much of an improvement over the 800 as the new levels have averaged, it will give a noble future to the mine. Horn Silver stock is quoted firm at \$6, and the high intrinsic worth of its shares was practically proven by its slight fluctuation during the recent crisis. Its eighth level is reported as opening up wonderfully well. Their new hoisting works will, when completed, be the most perfect in Utah and a credit to any mine. In this connection, it is but just to say that praise is due to Supt. Hall, whose careful, judicious management, both of underground and surface work, cannot but commend itself to his company. In addition to this fact, it may also be said that his independent, gentlemanly bearing has won for him the friendship of the camp. Most satisfactory results are being effected at the Rattler mine in the Carbonate camp, under the common-sense superintendence of Mr. John A. Kirby. Manager Bigelow is quoted as having reported more efficient and profitable work, with the present small force, than was produced at any time under the W. W. Clark mismanagement.

SANDSTONE DISTRICT.—*Salt Lake Chronicle*, May 28: A fine specimen of ore from the claim of Dr. Standart, in the Sandstone district of Lower Crossing, has just been received by that gentleman. In appearance it is very similar to the rock in some of the Silver Reef mines, and carries both silver and copper. Assays show 70 ounces silver and 8 per cent copper. This is from a four-foot vein, and it is the intention to make a shipment shortly and have the value of the ore thoroughly tested.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns,

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Branton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars. Improved form. Bullion and Copper Mouths and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail.

HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,700 feet long; Mary Murphy mine, Col., 6,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Plain Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

WORTHINGTON MINE PUMP.

ALEXANDER L. HOLLEY, being duly sworn, says: I am by profession a civil and mechanical engineer. I have been especially employed during the last ten years constructing and managing works for the manufacture of Bessemer steel. I am now Consulting Engineer to the Bessemer Steel Works of Troy, the Cambria Iron Works, the Bethlehem Iron Works, the North Chicago Rolling Mills, the Joliet Iron and Steel Works, and the Edgar Thomas Steel Works. In all Bessemer Works the hydraulic machinery is the most expensive and the hardest worked part of the plant. Any delay or serious fluctuation in its operation is fatal to the commercial success of the Bessemer process. After extensive acquaintance with the WORTHINGTON ENGINES, and with all such other forms of pumping engines as have been applied to the purposes required, I have adopted it exclusively, and to my knowledge it is adopted in every Bessemer works running or building in America. I have also, for the same reasons, adopted the WORTHINGTON PUMPS for feeding boilers.

Will contract to raise any required height single lift with our NEW PATENT MINE PUMP. Recent practical tests in Deep Mines of Mexico demonstrate this to be the BEST MINING PUMP extant. The largest stock of PUMPS for all purposes west of New York at our

BRANCH HOUSE, 30 and 32 First St., S. F.

LEWIS COMBINATION FORCE PUMP

POTATO BUG EXTERMINATOR

INJECTOR

A RARE CHANCE.

Is the Best Pump in the World. Another
New Improvement is Lewis' Patent
Spray Attachment.

Can change from solid stream to spray instantly. Regular retail price \$6. Weight, 4½ lbs. Length, 32 inches.

FOR SALE BY JOHN H. WHEELER,
111 Leldesdorff St., S. F.
P. S.—A sample can be seen at this office.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft

A party with \$20,000. to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying 400 lbs. per ton. At the center there is a dike or lift in the belt of the vein full 50 feet in width, and across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veinlets of quartz specked with ore. This mine is $1\frac{1}{2}$ miles northeasterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be in cash and the other half in mining the vein. The party accepting this offer will draw a prize ex-celled by none—yea, not even by the famous Silver King—for though it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

To Architects and Builders.

Valuable Vault for Sale at a Bargain.

A contractor has a thoroughly burglar-proof vault for sale. Dimensions, 43x5 ft.; height, 7 ft. in the clear; weight, about 6,000 lbs. In perfect order throughout. Double floors inside. Single burglar-proof outside door, 1½ inch steel and iron combined. The bolt work is of superior and first-class quality in all respects, there being no better on this coast. Can be examined at any time. Write for further information. Address P. 11., box 2361, S. F. P. O., or inquire at this office.

First-Class Stationary Engine For Sale.

Right or left hand; 10½x24 inch cylinder; fly wheel 3,500

Right or left hand; 10½x24 inch cylinder; fly wheel 3,500
pounds; nearly new and all in perfect order. Will be sold
at a great sacrifice for want of use. Terms of payment
easy; on installment plan, if desired. Original cost
\$3,200. Can be seen in position any day. Address H. M.,
Box 2361, S. F. P. O.

OUNDRY COKE. CUMBER

Scientific, Mining and Other Valuable Books.

PUBLISHED OR ISSUED, WHOLESALE AND RETAIL, BY DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenic, and Gold and Silver generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published embracing the subjects treated. Its authority is highly esteemed and regarded by its readers; containing, as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ore without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 150 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$3, cloth, postage free.

An Easy Binder.

A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held nearly as, in a cloth-bound book. It is durable, and so simple a child can use it. Price, (size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co.'s journals, Harper's Weekly, and Scientific American), 85 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Gold Medals for Best Truss in Existence.

The I-X-L ELASTIC TRUSS has

Cured more cases in the short period of its existence than all others combined during the last century. Has the Universal Joint movement in the Pad (ball and socket adjustable), making it the most positive retainer, combining comfort and ease, ever invented, and performs miracles where all others fail. Indorsed by the Medical Faculty of the world. This Truss is not a magnetic or electrical humbug, but an intelligent RADICAL CURE TRUSS. I-X-L ELASTIC TRUSS CO., Main office, No. 646 Market Street, San Francisco, Cal.

First-Class Stationary Engine For Sale.

Right or left hand; 10 1/2 x 24 inch cylinder; fly wheel 3,500 pounds; nearly new and all in perfect order. Will be sold at a great sacrifice for want of use. Terms of payment easy; on installment plan, if desired. Original cost \$1,200. Can be seen in position any day. Address H. M. box 2361, S. F. P. O.

THE AMERICANIZED ARASTRA.

Within the past year this machine has received some very VALUABLE IMPROVEMENTS, and which allows more work to be done at no additional expense. This Arastra, with a rock crusher, makes a very cheap, practical, and certainly profitable mill.

About Obtaining Patents.

Patents are Virtually Contracts

Between inventors and the public. The consideration flowing from both parties to the contract is expressly fixed by statute. The Government requires the following consideration in every case: First, that an applicant for a patent shall disclose a new and useful improvement, of which he is the first and original inventor. Second, that the invention has not been patented, or published in a printed publication prior to the date of his invention. Third, that the invention has not been in public use, or on sale, more than two years prior to his application for a patent. Fourth, that the invention shall be properly described and claimed in the specification forming a part of the patent. Provided an inventor complies strictly with these conditions, the Government guarantees that the inventor shall have the exclusive right to make, use and sell the thing invented for the term of seventeen years.

The Patent Law provides that in case a patent, which is the evidence of the contract, is not executed in compliance with the requirements of the law, it may be annulled and rendered void. Hence, it is of the greatest importance to every inventor that his patent or contract be skillfully and accurately drafted, that it may afford him complete protection for his invention during the life of his patent.

Secure a Good Patent.

An inventor should first ascertain whether or not his improvement has been patented or another. This requires an exhaustive search among all the patents in the class to which the invention relates. This question can often be answered gratuitously by us, immediately on receiving full information of the invention, by reason of our long and extensive practice as patent solicitors and editors and publishers of first-class scientific and industrial journals, during the past 20 years and over. When the question of priority of invention is not so readily to be determined, it is generally best to make what is termed a "preliminary examination," by searching through the patent office reports among the patents in the class to which the invention relates, and referring to our extensive patent library, containing compilations of special classes of American and foreign inventions, mechanical dictionaries, scientific encyclopedias, files of scientific and mechanical newspapers, and an immense number of patent applications by inventors of the Pacific coast, carefully filed by this office since 1860.

If, by this "preliminary examination," the improvement is found to have been previously invented, our client will receive, for the small sum of \$5 for the examination, a verbal or written report showing definitely whereby his invention has been anticipated, thereby saving him further expense and perhaps much time, useless delay, anxiety, etc.

To avoid all unnecessary delay, however, in securing patent at the earliest moment practicable, inventors will do well to forward a model, drawing or sketch, with a plain, full and comprehensive description of their invention (stating distinctly what the particular points of improvement are), with \$15 as a first installment of fees. If the improvement appears to us to be novel and patentable, the necessary papers for an application for a patent will be prepared immediately, and forwarded to the inventor for his signature. When the inventor receives the application and finds it duly prepared, he will carefully sign and return the same plainly addressed to us, with postal money order of express receipt for our own fee. The case will then, be promptly filed by us in the Patent Office, and vigorously prosecuted to secure the best patent possible. [This course is the most expeditious and satisfactory, as no time is lost in transmitting correspondence relative to the preliminary steps to be taken.] When the patent is allowed the inventor will be duly notified, and on sending the final Government fee of \$20 to us, we will order the issue of the patent, and forward the same as soon as it is secured from the Patent Office.

The payments are thus divided and made easy. We make no pretense of doing cheap work, in order to entice custom, nor do we afterward make additional charges to bring the bill up to a fair compensation. We do our work honestly and thoroughly, and we never give a case up as long as there is a chance to obtain a patent. The Agency charge is from \$25 to \$30, or sometimes more, if the invention is intricate or complicated, or requires much labor. Drawings cost from \$5 upward, according to their number and the time employed, and, if a model is sent, the express charges upon this and the papers must be added. The total cost, in addition to Government fees, rarely exceeds \$40, and for this we do all we can without appealing the case.

When the invention consists of a new article of manufacture, or a new composition, samples of the separate ingredients to make the experiment and also of the manufactured article itself, must be furnished.

Models and Drawings.

Models are now seldom required by the Commissioner of Patents, and generally only in intricate cases. Perfect drawings of practical working machines are considered more satisfactory to the Patent Office than the old and more cumbersome system of storing up an immense bulk of almost numberless models.

Drawings or sketches, sufficient to illustrate clearly the invention, with a sufficient description to enable us to make a full set of perfect drawings for the Patent Office is all that we require. A model will answer our purpose as well however, in cases where the inventor can more easily furnish it for use.

The value and even the validity of a patent often depends on the character, clearness and sufficiency of its drawings. There are thousands of existing patents in which the improvements are but partially or very poorly illustrated in the drawings. When an attempt is made to dispose of such patents, the vagueness and defects of the drawings often prejudice capitalists and manufacturers against the invention while in reality it may be of great value, and would meet with ready sale had the invention been fully portrayed by artistic and skillfully executed drawings. Again, when patents of this character are brought into court, the uncertainty and ambiguity of the drawings enable the opposing experts to mystify the judges as to the construction or combination of parts tended to be covered by the patentee. In all cases proper by us, the drawings are made under our personal supervision, by skilled draftsmen in our constant employ, and every precaution is taken that the invention fully and clearly shown by different views, so that the improvement will be readily understood by the examiners in the Patent Office, and comprehended by the public when the patent is granted.

In the Patent Office

The application is assigned to the Examiner having charge of the class to which the invention relates. The case must then take its turn with others in the order of filing, and is then carefully examined to test the novelty of the invention.

If the examiner fails to find anything that anticipates the invention, a patent is immediately allowed, provided the specification and claims are drafted in proper form. Should the Examiner find a prior patent which, in his opinion, anticipates one or more of the claims in the application, a letter of rejection is sent to the attorney in charge of the case; and, if the attorney coincides with the views of the Examiner, the claims rejected are erased. In preparing applications for patents, an attorney should be careful to familiarize himself with the class of inventions to which the application pertains, so that the specification and claims may be drafted as nearly perfect in the first instance as is possible. This course saves much time in prosecuting the application to a patent.

When claims are improperly rejected in patents which do not anticipate the spirit or wording of the claims, proper steps are immediately taken to convince the Examiner of his error. This is done, in most part, by personal arguments, as the differences in construction, operation, function and results are more readily discovered and appreciated by an oral presentation of the facts than can possibly be done by relying solely on written arguments. In order that the Patent Office record of the patents shall be complete, a verbal argument is generally supplemented by a manuscript brief, that others, in examining the files at any future time may clearly comprehend the position taken by the Examiner and attorney in prosecuting the case to a patent.

In addition to our own personal attention to the interest of our clients here, we have, for over 12 years past, had constantly in association with us in Washington, one of the soundest legal counselors and ablest of practitioners in patent business in this country, who carefully attends in person to our business at the Patent Office, and has attained success in a most marked degree.

Perfect Claims.

The value and force of a patent are dependent on its claims. A patent may disclose to the public the most important and valuable invention, and yet the claim be of such meager scope that the patent is actually worthless. When the claims of a patent are so loosely drafted that infringers can flood the market with improvements, differing from the improvement disclosed by the patent only in slight changes in construction and arrangements of parts, such a patent is valueless to the owner, as it fails to afford him that exclusive and complete protection guaranteed by the Patent Law. Hence it is that the greatest care and perseverance are required, first, in properly drafting the claims in the first instance, and second, in prosecuting the application before the Patent Office, and maintaining the rights of the inventor to claims as broad and sweeping as the invention will warrant. This latter is no easy task. The examiners of the Patent Office serve in the capacity of attorneys guarding the interests of the public. It is their worn duty to exercise the greatest care and watchfulness, that patentees do not secure claims of greater scope than they are justly entitled to. It is but natural that examiners are sometimes in error as to just what scope should be accorded an invention. Although the examiners act under honest convictions in cases where they refuse an inventor his just rights, yet it is the duty of the attorney to maintain the claims of his client, if he is convinced that they are just and proper. To succeed in this requires the display of tact, firmness and ability; and when the Examiner is made to see that the inventor is honestly and fairly entitled to the claims which have been rejected, he will almost invariably recede from his former action, and allow the case.

Advantages to Inventors on the Pacific Coast.

The firm of DEWEY & CO., (continuously editors and publishers of the MINING AND SCIENTIFIC PRESS, nearly from its early commencement in 1860) offer comparatively far better facilities to the local inventors of the Pacific States and Territories than are possessed by any other agents in America. Members of the firm give personal attention to the applications entrusted to their care. They have been longer in practice in patent soliciting than most agents who are still personally engaged in the business. They have secured more U. S. and foreign patents in the past 20 years (with very few exceptions) than any other firm still existing. Their practice has been so successful and long continued, that the great majority of inventions on this side of the American continent have been patented through their agency, thus affording them great and valuable experience, by thorough information of the true principles and points of novelty in the inventions, whether general in character or peculiarly local to this coast.

The extensive business consultation and experience of this firm, is undoubtedly one of the most fortunate in existence for affording inventors prompt and reliable advice, and the best possible facilities for securing their full patent rights with safety and dispatch at uniformly reasonable rates.

Every patentee of a worthy invention is guaranteed the gratuitous publication of a clearly-stated and correct description of his invention, in one or more of our influential and reliable newspapers, affording just the circulation that is best calculated to widely inform the class of readers most specially interested in the subject of his invention.

Saving of Time. Etc.

Inventors on this coast will find that owing to our familiarity with inventions and local affairs of this coast, we can more readily and fully comprehend their wants, and thus save much of the time ordinarily consumed in preliminary writing back and forth when distant agencies are employed.

Caveats.

A caveat is a confidential communication made to the Patent Office, and is therefore filed within its secret archives. The privilege secured under a caveat is, that it entitles the caveat to receive notice, for a period of one year, of any application for a patent subsequently filed, and which is judged to be novel, and is likely to interfere with the invention described in the caveat, and the caveat is then required to complete his application for a patent within three months from the date of said notice. Caveat papers should be very carefully prepared. Our fee for the service varies from \$10 to \$20. The Government fee is \$10 additional.

To enable us to prepare caveat papers, we only require a sketch and description of the invention.

Rejected Applications.

Inventors who have rejected cases (prepared either by themselves, or for them by other agents), who desire to ascertain their prospects of success by further efforts, are invited to avail themselves of our unrivaled facilities for securing favorable results. We have been successful in securing Letters Patent in many previously abandoned cases. Our terms are always reasonable.

Inventors who do business with us will be notified of the state of their application in the Patent Office, when it is possible for us to do so.

STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),
(Signed) RICHARD T. MARSH,
Managing Director.

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

ST. LOUIS, Mo., Sept. 28, 1883

Messrs. Adolphus Meier & Co.—GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER BUSCH BREWING ASS'N.

OFFICE OF Supt. of ROYAL RAILWAYS, BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 21, we respectfully inform you that the three boilers built under your patents under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

(Signed): BRAUKE.

The PACIFIC WATER JACKET SMELTERS embrace many features that are entirely new and of great practical utility, which are covered by letters patent.

No other furnaces can compare with these for durability and in capacity for uninterrupted work.

MORE THAN ONE HUNDRED of them are now running on the Pacific Coast, giving results never before obtained as regards continuous running, economy of fuel, grade and quality of bullion produced. We are prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requiring no brick or stone work, except that for the crucible, thus saving great expense and loss of time in construction.

Complete smelting plants made to order of any capacity and with all the improvements that experience has suggested as valuable in this class of machinery. Skilled and experienced smelters furnished when desired to a superior intend construction and running of furnaces. Estimates given upon application. Send for circular.

THE ROLLER ORE FEEDER

Patented May 28, 1882.

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.
A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 20 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the so-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringers.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Mining and Mechanical Engineers.

It is a matter of remark that while the mechanical appliances of mining, the hoisting and pumping machinery, mills, furnaces, etc., have been very greatly improved in the last ten or twenty years, the improvements in mining methods are by comparison few. In the mechanical branches of mining the mining engineer has had at his disposal the improvements in machine construction effected by the united labors of mechanical engineers throughout the world, and he has not been slow to adapt to his requirements the improvements in steam engineering and all the miscellaneous mechanical inventions. The number of engineers and inventors engaged in mechanical work is very large; the number of mining engineers comparatively small, and the incentives to invention among the latter are not so great. Again as there is always a large amount of machinery to be designed, erected and kept in repair, at extensive workings, a mechanical engineer is frequently chosen to superintend the mining work and without knowing or caring much about mining, he is placed in the position which should be occupied by an expert mining engineer.

The truth is, the mechanical engineering ought to be done by mechanical engineers and the mining operations by mining engineers. One great trouble with us has been that there have been altogether too many with a partial knowledge of both professions, and a thorough one of neither. Moreover, a great deal of the credit really due to mechanical engineers has been taken by men who happened to be mere superintendents, and who, from merely giving an idea of a general plan, were supposed to have worked out the details which really ensured success. Of course it cannot be expected that the mechanical engineers will devise many new mining methods, while the mining engineers do devise new mechanical plans. It has become too much the custom to have the mining engineer attend to what are really the duties of a business superintendent, such as paying bills, looking out for pay-rolls, correspondence, etc., which occupy so much time that he cannot attend to his legitimate duties. And many persons suppose that the man who can do these things well is really a mining engineer, which is far from being the case. A mining superintendent is not by any means always a mining engineer. There are hundreds of people who assume the title without any right to it.

The American Society of Civil Engineers convened at Buffalo on Tuesday. About 4,000 delegates were present. Papers were read by distinguished members on engineering questions. Resolutions were passed asking President Arthur to appoint President Whittimore a delegate to the International Standard Time conference. The Nominating Committee consists of G. S. Fields of Buffalo, A. Fink of New York, George Gray of San Francisco, F. E. Kieffer of Ottawa, and Henry Flagg of St. Louis.

The Manhattan Silver Mining Company, of Austin, employs 115 surface men and 121 miners on day's pay, 35 contractors, 404 tributors and 48 leasers. The mills reduced in the last week a trifle over 118 tons, of the assay value of \$37,427.85.

Encourage the Prospectors.

It is the duty of every one, at all interested in the mining industry of the country to encourage the prospectors in every possible way. They are the men who find the mines; they do the preliminary work so essential in making a good mine, to wit: First find your mine. Capitalists never find a mine; it is the prospector who does it. The capitalist develops it. We hear a good deal about encouraging capital but not so much about encouraging prospecting; whereas, if there is not first found a claim there is nothing for the capitalist to do. This great pioneer in mining fields—the prospector—does really more hard work for less pay

work. It is one of the prime characteristics of the class that prevents them—not laziness. They are prospectors, not mine developers. They have no money for this. Very few dollars are needed to carry on their business. Their grub costs little, lodging nothing, and transportation nothing.

But to open and prove the real value of a mine takes money. The prospector is willing to take a comparatively small sum for his prospect for the very reason he knows it is little use to him. Of course we speak of quartz. There are few sections for placer ground in these days.

The prospector, then, has a definite duty to perform in the body politic. He is as necessary

THE DAVIS' KEY SEATER AND SLOTTING MACHINE.

than any other class of working men. Yet strange to say, many look upon him as more or less of a nomadic vagabond with no settled occupation, and who is mainly waiting for something to turn up.

The real prospector of the mountains is by no means an idler, or a vagabond. In the winter months he must hibernate; once the snow is off, he has plenty to do to occupy him. So far from being but a mere wandering miner, or a hanger-on of mining camps, his is a real business. Many good miners are very poor prospectors, and there are lots of prospectors, who cannot be persuaded to stick to work with pick and gad underground. They will shoulder their blankets, and few tools, however, and tramp over the mountains for months, camping here and there and looking carefully all the time for prospects.

Once the claim is found, however, the charm is gone. The man wants to sell this and hunt for other claims. Then is the chance for the man of capital. Before that he is of no use. His time comes when the claim is found. And because these prospectors do not develop their claims or work them at all steadily, some people profess to think they are lazy and will not

in his chosen field as the capitalist in his. Our mining regions are discovered by him—our rich mines really found by him. It must be only, therefore, the thoughtless or the ignorant who see in the prospector a vagabond or a tramp. He is neither. Honest as the day is long, simple in habits, persevering and hopeful, the prospector is one of our pioneers of civilization to whom the country owes a debt of gratitude.

MINING FOR WATER.—The Quijotoa Prospector of May 31st says: There are 10,000 pounds of machinery at Casa Grande, consisting of boilers, pumps, piping, etc., for use at the Bonanza Mining Company's well. We understand that a large double-compartment shaft will be sunk, and drifts run from the bottom. A series of pumps will be placed in the shaft, and the water question thus thoroughly tested as to the quantity available.

A TECHNICAL commission on the Suez canal, to discuss the question whether a second canal parallel with the present one shall be built or the present canal enlarged, will soon be appointed. The commission will consist of eight English, eight French, and six other engineers.

Technical Society of the Pacific Coast.

At the regular semi-monthly meeting of the new society on Friday of last week, Mr. W. W. Hanscom, mechanical engineer, read a paper on "Cable Railway Propulsion." Tables were given showing the comparative weight of machinery and weight of cables on all our local roads, the horse power to drive cable; pounds of cable moved per horse power; proportion of power required to drive cable; average power for cars; horse power for each car; average speed; average distance passengers are carried; average power, for each 1,000 passengers carried; total power for cable, for cars, and for passengers, etc.; some very interesting facts were elicited. On an average of all our roads it takes 68 per cent of the power to drive the cable alone; 23 per cent to move the cars and only 4 per cent to carry the passengers. Aug. J. Bowie, Jr., mining engineer, read a paper on "The Measurement and Flow of Water in Ditches." He described the California miner's inch as it varies in different localities, and gave the determination of the inch experiments at Columbia Hill in this State and those at La Grange. He then gave the formula to determine the flow of water in open channels, co-efficients for roughness, etc. Mr. Bowie gave several examples of the value of co-efficient in ditches, and brought out numerous valuable facts which have been suggested in our experience in mining ditches, etc., in this State, giving examples of the loss of water in various ditches while flowing from one end to the other. The subject is one of which Mr. Bowie has made a study for some years, and his conclusions are valuable to the engineering fraternity. We shall publish these papers when the drawings are prepared.

Key Seating and Slotting Machine.

Among new tools of interest to iron workers is the Davis patent key seater and slotting machine, a representation of which is given on this page. It will be noticed in the general design that the frame is made of one casting together with the ways, and therefore very strong and cannot get out of line. The connecting rod is so arranged as to keep chips and dirt from falling into the crank-pin. The gears are all cased, and therefore are in no danger from anything getting into them. This casing is not shown in the cut. The ways are bored out and the top of frame faced by putting the frame in a mandrel and facing up the top of the column in the lathe; the top is planed on both sides, and by this arrangement every part is brought perfect and true.

The saw clamp is handy, and requires but a short time to change cutters. The stud pins to clamp are provided with washers, and so arranged that the clamp can be placed between them at any height required, and will not drop down. A very simple arrangement is also furnished to give any desired draft to the key seat required. It can also be made any depth, and every one can be the same. This is a very desirable point, and is now made to work so perfectly that this machine can be used in all shops where key seating is required. The pulleys are 13 inches in diameter and 4½ inches face. This machine will cut from one-fourth inch to one inch key seats, and work very fast. The Perry & Place Machine Company are agents for this coast.

Electric Currents in Mines.

At a recent meeting of the Manchester Geological Society, Mr. John Knowles read a paper "On the Descent of Electric Currents into Coal Mines." During a thunderstorm which took place on the 21st of February last, a distinct shock was felt in the workings at the New Rivin Pit, Little Lever, near Bolton. The colliery was situated close to Hall-lane, the main road between Moses Gate and Radcliffe, and about three miles from Bolton. The upcast pit being about 30 yards from the road and the downcast, 50 yards. The upcast pit was 9 feet in diameter inside the brickwork, which rose as a chimney about 24 feet above the ground. In this pit there was no winding, but there was one pulley 5 feet in diameter, which stood without rope, to be used with a portable capstan engine in case of emergency. There were also two folding iron doors, which took up a space in the chimney 8 feet high by 5 feet wide. The pit was 97 yards deep. The downcast pit was also 9 feet in diameter and 97 yards deep, with a sump of 14 yards further. In the pit were four iron wire guides, 1½ inches in diameter, and two iron wire ropes between the cages; the former went into the water at the sump, and the latter terminated just below the landing plates. There were also a bell wire of galvanised iron, and 3 in. steam pipes, which were mostly uncovered. The two cages were made of iron, a steel rope being used for one cage and an iron rope for the other. This pit was surrounded with the ordinary cast plates and rails, but there was not any connection with the chimney of the upcast shaft. There were the usual buildings about the pits, viz., engine-house, hoilers and cabins; also a chimney 6 ft. square and 20 yards high, but no lightning conductor on it. At the bottom of the downcast pit there were the usual plates and rails, with the steam pipes extending to two engines on the east side and one on the west. Those going eastward were laid up a brow, with a gradient of one in three, to the Lower Three Yards mine, and then a short distance on a level to the first engine, which wound up the down-brow in this mine. At this point there was a rise tunnel to the Lower Yard mine, worked as a self-acting incline. The steam pipes were carried to the top of this tunnel, and then on a short level to the engine at the top of a down-brow in the Yard coal, where a wire rope was used to wind the coal to that point. There was also a wire rope used in that brow to work a small pump, which forced water to the top of the incline, whence it ran to the pit.

On the west side the steam pipes were laid on a level in the Lower Yard mine to a small engine, which wound coal up a dip tunnel from the Lower Three Yards mine. This engine had a 6 in. cylinder, with 10 in. stroke, the dip tunnel being 48 yards long with a gradient of 1 in 5. The electric current appeared to have struck the chimney at the top of the upcast pit, about 2:30 p. m. on the day named. It displaced a large quantity of brickwork, and then came down outside the chimney, striking the ground close to it and making a large hole. It then went along the ground to the cast plates at the top of the downcast pit, and it was presumed went down the steam pipes and so into the workings—on the east side going through the Yard down-brow engine, and along the rope to the wagons, and on the west side passing along the pipes to the engine, where the manager was standing. The strength of the current must have been very great, as experienced by a wagoner seated 4 or 5 yards from the bottom of the downcast, as he stated that he saw a brilliant flash, and heard a great noise, which sounded as if in the pit. He had the heel of his clog on one of the plates at the time, and felt a tingling sensation in his leg, which lasted a day or two, and the sole of his clog was burnt, as if hot irons had been drawn over it. Other men in the pit also experienced a sensation which they described as resembling a shock received at an electrifying machine. The manager, who was on the west side in the Lower Yard mine, at a small engine 300 yards from the pit, had his hand on the steam handle and felt a shock which numbed him for a few seconds, so that he could not see or move, and was afterwards so completely prostrated by the effects of the shock that he was confined at home to bed for six days before he was able to get up and walk.

From the statements which had been made by the men it would appear that there must have been a very strong current of electricity passing down the ironwork of the pit, and it was fortunate that much of it was distributed before it reached the workmen in contact with any metal. The manager being the nearest in direct contact seemed to have suffered the most, as the wagoner was only connected with the plates by a wooden clog, and others at the bottom of the Lower Yard coal incline only received a shock after it had passed many means of distribution. Two other cases of a similar kind had occurred—one at the Tanfield Moor Colliery on the 12th July, 1880, on which a paper was read before the members of the North of England Institute of Mining and Mechanical Engineers, and the other at West Thornley Colliery, on the 11th December, 1883, with regard to which a paper was also read before the same society.

The miners at Cœur d'Alene are jumping the claims which are idle and which were located by proxy.

Phosphorus in Iron.

Frank Julian, Iron Mountain, Michigan, read before a recent meeting of the American Institute of Mining Engineers the following note "On the Determination of Phosphorus in Iron:

After the solution of an iron ore, or metallic iron, in an acid, for the determination of phosphorus, it is necessary to evaporate the solution to dryness and to heat the residue to effect the complete separation of silica. Authorities differ as to the temperature required, some recommending not over 100° C., others as high as dull redness. For the purpose of securing some indications as to the degree of heat which may be safely or advantageously employed I selected a gray pig-iron, a piece of Bessemer steel rail, and a sample of Ludington ore having the following composition, the phosphorus in the pig and steel being determined by Gintl's ferric chloride method:

Twenty-five grams of the ore, having the composition A, was dissolved in hydrochloric acid, and filtered into a 500 cc. flask. There was added 3.1 grams of silicate of sodium and 1.155 grams crystallized phosphate of sodium, and the liquid made up to the mark.

Twenty-five c. c. of this solution, having the composition B, 1 gram of the pig, and 2 grams of steel, were taken for each determination. The metals were dissolved in 10 c. c. and 20 c. c. of nitric acid, specific gravity 1.25. After heating the dry residue, it was dissolved in the least possible quantity of hydrochloric acid, which was replaced by evaporation with 25 c. c. of concentrated nitric acid, and precipitated with a 7 per cent. nitric acid solution of molybdic acid. After solution of the phospho-molybdic silica was separate, and any adhering phosphorus recovered. The magnesium precipitate was always reprecipitated to free it from molybdic acid (traces of which invariably adhered to the first precipitate) weighed as pyrophosphate, and corrected for solubility. Great care was taken to have all the conditions of each determination as nearly identical as possible. The following are the results obtained:

No.	Temperature.	Pig.	Ore.	Steel.
1.	No evaporation.
2.	95° C. 1 hour.	.341	.407
3.	110° 12 hours.	.375	.400	.137, .139, .132
4.	125° 1 hour.	.377	.401	.157
5.	170° ½ hour.	.444	.401
6.	125° 2 hours.	.453
7.	170° 1 hour.	.456158
8.	220° 1 hour.	.456	.398
9.	350° 1 hour.	.453	.398
10.	450° 1 hour.	.456	.398

In No. 1 the steel was dissolved in acid, and the molybdic solution added at once. No. 2 was the heat of a water-bath; No. 3 steam pipes; Nos. 4, 5, 6 and 7, an air-bath; Nos. 8, 9 and 10 fused-metal baths. The first four, in each case, dissolved readily and completely; Nos. 5 to 8, completely, but with difficulty; while Nos. 9 and 10 required much acid and a prolonged digestion, and a considerable quantity of ferric oxide remained undissolved.

While somewhat different results will undoubtedly be obtained from other samples, I think the following conclusions may be safely drawn:

	Pig.	Steel.	Ore.	A. B.
Comb. carbon.	.64	.569	Silica.....	3.39 sol. 1.00
Graphite.....	2.40	Phosphoric acid.....	1.007
Silicon.....	2.85	.077	Sulphuric acid.....	trace.
Sulphur.....	.06	Alumina.....	.79
Manganese.....	.51	.022	Lime.....	.85
Phosphorus.....	.450	.165	Magnesia.....	.51
Iron, etc.....	92.081	97.970	Manganese ox.....	.62
			Ferric oxide.....	95.37

1st. That a temperature of at least 125° C., for two or three hours, must be used where the amount of silicon or silicic acid is at all large.

2d. That any temperature short of dull redness may be employed without interfering with the accuracy of the determination; the heating with an acid reverting any meta- or pyro- into ortho-phosphoric acid; but that a temperature of from 125° to 170° is to be preferred, as saving time and acids in re-solution.

3d. That the silicon in metallic iron is much more prejudicial to the complete separation of phospho-molybdic than the silica from a soluble silicate.

THE TWIN PROSPECTS.—The ore vein in the Found Treasure continues to improve. The incline is down 23 feet, and the vein has widened gradually, but uniformly, with every foot of depth attained. There is now nearly a foot of rich chloride ore, which will probably mill from \$300 to \$500 per ton. The ledge itself is about 4 feet in width, and the main vein is on the foot-wall, although there is a narrow streak of the same quality of ore close to the hanging-wall. More hands will be put on this evening, and the work will henceforth be prosecuted night and day. The owners of the Mayflower have commenced an incline close to the Found Treasure line, and at a depth of 8 feet have a vein 10 inches in thickness of the same character of ore as that being extracted from the adjoining location. The incline is about 175 feet from that of the Found Treasure, and is undoubtedly on the same ledge. The discovery in the Mayflower renders it pretty certain that the ore vein is continuous through the intervening ground between the two inclines. These, so far as developed, are the most favorable surface prospects that have ever been encountered in this section, and if they continue on down, as present appearances indicate the probability of, they will in the near future produce a sufficient amount of ore to keep all of the stamps in the district in continual agitation.—*Tuscarora Times-Review*.

The Black Hills.

What is termed the Black Hills country is all that part of Dakota lying south of the 45th parallel of north latitude and west of the 102d meridian, and all that part of Wyoming lying north of the 43d parallel and east of the 105th meridian, and embracing about 22,500 square miles, or 14,500,000 acres, of which about one-fourth is agricultural, the other three-fourths being mineral and pastoral lands. About 400,000 acres, all of which are in Dakota, have been taken under the homestead, pre-emption and timber culture acts. The balance is now open to settlement, with the exception of a small portion lying east of the banks of the Cheyenne river and the 103d meridian. The farming lands of the hills are as productive as can be found any place in the world. Fifty bushels of wheat, 60 of barley, 110 of oats, 400 of potatoes and 600 of onions have been raised per acre of ground. All other kinds of vegetables do equally as well; potatoes that will weigh two or three pounds are common, and some have been raised that went as high as four pounds. The soil is a rich vegetable mold, strongly impregnated with gypsum, of which there is an inexhaustible supply, and consequently the land need never become impoverished.

Gold mining is carried on from Bear gulch on the north to Custer City in the southern part of the Hills, a distance of 90 miles, and from Rockford on the west to Rockerville on the east. In no other country in the world are there so many and extensive mines of gold as in the Black Hills. From the northern to the southern, and from the eastern to the western extremity, gold is found in nearly every gulch and on every hill within the mineral belt. In other mining countries it is only found over a small area of country, covering but a few miles of territory at the most. Here there are about 1,200 square miles in what is called the mineral belt, and gold is found in almost every square mile of the 1,200. The lodes vary in size from 10 to 1,000 feet in width, and some as much as 50 miles in length. The great majority of the mines are low-grade ore, but with the immense bodies of pay ore and good management these mines have been made to pay better than any other in the United States. Ore that will go \$2 a ton will pay to work, while that which goes from \$4 to \$10 per ton will pay largely. The ore which is worked by the great Homestake mills, at Lake City, does not average \$7 per ton, yet that company have paid 51 successive monthly dividends, part of which have been \$30,000 per month, and the balance \$40,000, besides having a large surplus on hand after paying all expenses. These mines are better developed than any others in the Black Hills, but equally as good and extensive mines have been discovered.

The quartz mills are the largest and most complete in the world; nearly all have from 40 to 120 stamps.

The silver mines of the Hills are all of a high grade. Those of Galena have been worked continuously ever since 1876, and the ore shipped by wagon to Sidney, 250 miles, thence by rail to Omaha, Nebraska, for treatment. At the carbonate camp, seven miles west of Deadwood, rich carbonate mines have been opened, the ore from which is now being shipped to Omaha and Denver.

Rich and extensive copper mines have been discovered in several localities.

The mica mines of the Black Hills are all in the vicinity of Harney's peak and Custer City. They are easily worked, requiring very little capital. All that is necessary to work a mica mine and get the mica ready for market are a pick, shovel, drill, powder and fuse and a large pair of shears, such as are used by tinners, to cut it in rectangular form.

On Box Elder, near Brownville and Rockford, are several large veins of iron, with millions of tons in sight. At the latter place it carries from \$2 to \$10 per ton in gold.

On the north, south and west of the hills are hundreds of thousands of acres not used, owing to the cost of transportation.

Inexhaustible beds of gypsum encircle the entire Hills, just inside the foothills and outside the main Black Hills. At present it is only used by plasterers. With the advent of railroads, it will be shipped to the States east of the Missouri river, there to be used as a fertilizer on their worn-out land.

Petroleum is found on the west side of the Hills in Wyoming Territory, near the boundary line between Dakota and Wyoming. No works have as yet been established for refining. It is only used for lubricating purposes by the Home-take and other companies at their mills. Salt springs are situated about eight miles northeast of the oil springs and in Wyoming Territory. Salt for the entire hills is manufactured here, and sold on the ground for two cents per pound.

Marble of a beautiful purple color is found near Rapid City and Custer, and sandstone, granite, slate, porphyry and limestone is plentiful, and is found in every part of the Hills.

The Black Hills is a well watered country, being drained by the forks of the Cheyenne river and their tributaries. On hot Spring creek in Custer county are situated mineral springs which are fast acquiring a reputation for curative powers second to none in the United States. The average temperature is 95 degrees Fahrenheit.—*Custer Chronicle*.

Underground Haulage.

The subject of underground haulage, to which comparatively little attention has been paid on this coast, is one of increasing importance among the extensive mines of Great Britain, particularly in the Lancashire coal field, where the great depth of the mines has led to large areas being worked from each shaft. The economical transportation of the coal from the working places to the shaft has become a matter of great necessity. At the collieries of the Astley and Tyldesley Coal and Salt Co., in the older and shallower pits the various systems of haulage comprise self-acting planes, single down-brow ropes, main and tail and endless ropes, the engines in each case being placed underground and supplied with steam through pipes in the upcast shafts. In some cases horses are entirely dispensed with, and in others were used for hauling the coal from the workings along the levels to the main down-brow ropes. Mr. G. H. Pearce, at a recent meeting of the Manchester Geological Society, read a paper on the system of underground haulage at these collieries, giving extended details. A general statement of the plan will be of interest to miners here. At the Gin pit the hauling engines consisted of a pair of horizontal high-pressure engines, with cylinders 10 inches diameter and 2 feet stroke, geared 3½ to 1, and working at about 140 revolutions per minute, with a boiler pressure of 70 lbs. On the second motion shaft were placed two driving pulleys, each 6 feet diameter, with a clutch to enable either of them to be put out of gear. Each pulley had 4 grooves, and to obtain the requisite adhesion, the rope was passed 3½ times over the driving pulley, and a guide pulley with three grooves was put in front of it. By this mode of driving the friction on the ropes was reduced to a minimum.

The ropes were then passed round pulleys 6 feet diameter, fixed in the headgear and down the shaft in wood pipes. Upon reaching the respective mines, pulleys were fixed in the shaft, and the rope was taken along the centre of the main way round a pulley 4 feet diameter, fixed on a tram with a tightening screw at the extreme end of the plane, and it returned along the side of the road on pulleys and wood rollers. In each mine the system adopted was to run the tubs in sets of from thirty to forty, the rope being carried on the top of the tubs, and attached at each end of the tram by ½-inch chains about 7 feet 6 inches long, which were wrapped two or three times round the rope and back hooked. The distance to the station ranged from 700 to 1,300 yards, and the time ordinarily occupied in the journey from the shaft, changing at the end and returning, was from ten to fifteen minutes. The coal was all brought to the main rope either by gravitation or by haul from the working places. One of the principal items of expense in all underground haulage was the cost of ropes, and they attached great importance to the quality of the material and mode of construction. The standard size adopted for the hauling ropes was ½-inch diameter, and they were made with six strands of the best plough steel. The average quantity of coal hauled per day was 260 tons, but at least 400 tons could be hauled per day, and he estimated the cost of labour at 12s. 4d. per day, and of materials at about 1.321d. per ton. At the Nook pit they utilized a pair of engines for hauling, which were also used as capstan engines, with cylinders 12 inches diameter and 2 feet stroke, geared four to one, working at a boiler pressure of 45 lbs. At these pits, instead of each rope being brought to the surface, only the main driving rope worked in the shaft, and from it were worked the branch ropes into each mine, by means of grooved pulleys. In this pit they had been at some disadvantage in having to adopt the existing roads for rope haulage, as they were not originally laid out for that purpose. In one mine the rope was carried round curves at both ends of the shaft by deep flanged pulleys 4 feet 6 inches diameter, and at lesser bends by small pulleys, also with deep flanges. The road was also undulating, which necessitated the use of lashing chains at both ends of the train, which consisted of about five tubs each at short intervals. For an average quantity of 440 tons he estimated the cost of haulage at about 35s. per day for wages, and about 1.749d. per ton in materials for leading the coals an average distance of 1,400 yards.

THE body of Wm. H. Blythe was enshrouded when he died some 14 months ago, and placed in a hermetically sealed casket which was put in a sealed niche in the receiving vault. Owing to a desire on the part of relations in England, it was decided to photograph the remains. The casket was taken from the niche last week and unsealed. The body was found to be entirely free from any taint of decay. It was perfectly odorless, and the features were as full and the flesh apparently as sound as when it was placed in the casket. There was no shrinkage whatever. The face and eyes and the hair were all perfectly natural.

THE Pacific Improvement Company's steamer makes two to three round trips every month, bringing 4,000 tons of coal to this port on every trip.

THE production of the Calumet & Hecla, of Michigan, in 1882, was about 32,000,000 pounds, and in 1883 its yield was about 33,000,000.

MECHANICAL PROGRESS.

Improved Method of Producing Steel Plates.

Dr. Henry Muirhead, president of the Physiological Society of Glasgow, has recently brought before that body some particulars of a method of manufacturing steel plates for ship-building and boiler-making purposes, which is of much interest. It is the invention of Mr. Joseph Whitley, of Leeds, who has erected works for prosecuting the manufacture. Briefly describing the process, Dr. Muirhead said: "A hollow metal cylinder lined with gannister or other brick revolves at high speed, the axis being horizontal. A gutter or rhone perforated with holes passes into the interior along its whole length. Into this gutter is poured melted mild steel, which, escaping through the holes, is carried round by the swiftly revolving case, and centrifugally is formed into an inner cylinder of steel of an inch or more in thickness. This cylinder, while still hot, is drawn out, cut across by a saw, put into a rolling mill, and rolled to the length and thickness required." Mr. Whitley writes: "Suppose I wish a plate for ship-building; then, say, even a mold 5 feet in diameter and 5 feet long; in it I cast a cylinder an inch thick. This, when taken out and cut, is fully 15 feet long and five feet broad. It is then rolled down to half an inch in thickness. Such a plate is then 30 feet long and 5 feet broad, for we can arrange that the displacement of the thickness shall be chiefly endwise. The present mold is 9 feet long and 5 feet in diameter. With it I successfully cast a mild-steel shell—weight of metal about 30 cwt. This makes the long-looked-for, but now no longer doubtful, fact a historic fact in metallurgical science. Hitherto, these plates have been made from large ingots, which have been burnt on the outside while getting heated to the center. It is the overheated portion that gives way in collisions, boiler burstings, &c. In my process the whole plate is homogeneous throughout, and the tensile strength is so much increased that when ships collide there is no bending or fracture; and though the bilge is made to collapse, the ship, still floating can sail into port to get rebilged—recountoured. Of course, tubes of smaller size can be manufactured centrifugally, and these are especially suitable for connections about steam boilers, where in lap-welded tubes breakage is apt to take place at the overlap."

Perforated Feed Pipes.

Perforated feed pipes, having their delivery ends capped, are very pretty things in theory, but in practice, if the water used be anything but the very best, they are a source of continual trouble and annoyance. The small holes are very easily clogged with scale, and feed pumps are very frequently broken in the effort to force sufficient water into the boiler. The perforations may be stopped in two different ways: Firstly, by the formation of scale around them, which "comes down," as it is usually expressed, the hole gradually becoming smaller and smaller, until it becomes entirely closed up; secondly, by the lodgment in the end of the pipe of small pieces of scale, which, having been formed in the heater or some remote part of the pipe, has become detached, or "flaked off," and brought forward by the current of incoming water, and lodges in the end of the pipe in consequence of its being capped over, and gradually fills it up. In a case which occurred recently the feed pump was twice broken in the effort to keep sufficient water in the boiler before the cause of the trouble was suspected by the engineer in charge. A steam gauge placed between the boiler and feed pump indicated something over 100 pounds as the pressure required in the feed pipe to keep the boiler supplied with water when the steam pressure was but 60 pounds. Upon examination by the inspector, the perforations were found nearly closed by a formation of hard scale around them. The only remedy in such cases is to remove the perforated portion of the pipe, and discharge the feed water through the open end. If the pipes are properly arranged, no harm to the plates or seams will result, even if cold water is used; and unless the water be quite bad, it will be sufficiently well flushed by the incoming water to keep it quite clean for a long time.—*Locomotive.*

Progress in Locomotive Construction.

The locomotive of to-day is a giant by the side of the production of 1851. The New York Central express engine is a very Anak. Its weight is 84,000 pounds, or nearly two and a half times heavier than its above mentioned prototype. The cylinders are eighteen inches by twenty-four. The average man's head is far below the top of the driving wheels, which are seventy-five inches in diameter. In 1854 a New York express passenger locomotive traveled 25,000 miles in a year; last year the average mileage per engine stood between 70,000 and 80,000 miles. A locomotive for express passenger service costs, taking the experience of the past few years, from \$7,500 to \$10,000 to build.

In comparing the locomotives of to-day and a quarter of a century ago, you will notice that while the weight of the whole machine has increased greatly, certain of the dimensions have

not altered much. This is because we are limited in various ways in constructing a locomotive. We can not make the body of the engine over a certain width, because of the gauge of the track, not over a certain height, for we must keep the center of gravity at about the same position; not over a certain length because of the wheel centers. So the locomotive must always remain nearly the same in form. It is to increased capacity of boilers that we must look for increase of power. At present an express locomotive boiler is of eighty-horse power; that is, if it were in a stationary engine that would be its capacity. But when the locomotive is drawing a train of cars at five miles an hour, the boiler supplies the strength of 375 horses, and at forty-five miles an hour, the power expended is equal to that of from 700 to 800 horses.

STEEL NAILS.—The near approach of the manufacture of steel nails by the Bellaire (Ohio) Nail Works Company is attracting a great deal of attention, not only among the nail manufacturers of the West, but also among the workmen at the mills. As yet the works have been operated only experimentally; some nails have been cut, and it is expected that shortly they will be operated continuously as a steel nail works. It is also stated that the Riverside steel plant will be in operation about the 1st of June. This experiment on the part of Bellaire and Riverside will be watched with a good deal of interest. It is probable that no higher price can be obtained for these steel nails than rules for iron nails. It has been claimed that because the steel nails can be cut smaller—more to a pound than the iron nails, and be as strong as iron nails, therefore consumers will be willing to pay an additional price; but the value of a nail in many instances does not depend upon its strength, but upon the frictional resistance to the strain that would draw it out of the wood, and it is probable that the iron nail of the same size would have a greater frictional resistance than the steel, and certainly the larger iron nail would have a greater friction than the smaller steel nail. That steel nails can be manufactured, and probably as cheaply as the iron nail, cannot be doubted. The problem is, how will they take in the market.—*Industrial World.*

NEW STONE SAW. A new sort of saw for cutting stone is described in *La Semaine des Constructeurs*, which seems to have advantages over those now commonly in use, and is easily and cheaply made and operated. In place of the ordinary long steel blades, supplied with sand to enable to grind their way into the stone, the new machine presents only a slender endless cord, composed of three steel wires twisted together, which is stretched over pulleys in such a way as to bring the lower portion horizontally over the stone to be cut. The frame carrying the pulleys is movable, so that the cord can be brought into contact with the stone, or lifted away from it, at pleasure, and the whole is kept in rapid motion, while water falling in drops from a reservoir above serves to moisten the stone. The three wires which form the saw differ from the ordinary kind in being square in section, and by twisting into a cord they are so turned as to present a succession of oblique cutting edges, which act, when set in motion, in nearly the same way as so many small chisels, while the rapidity with which the blows follow each other probably adds to the effect.

POINTING STEEL.—To draw a piece of tool steel to a point may appear a simple operation at first sight, but unless care is taken it cannot be done. If the end of the bar of steel is concave in the slightest degree, it cannot be pointed. For in hammering it the surface steel is made to overrun the center, and causes the extreme end to be concave in a greater degree than when it was started, and so long as this concavity exists, the steel cannot take a fine point. Before commencing to draw the steel to a point, the extreme end of the piece of steel should be ground or filed to a rounded point, similar to a center punch, but not so sharp. When this is done, a point as fine as a needle may be drawn out. Care must be taken not to over-heat the steel, or it will crumble to pieces. It should not be heated above cherry-red heat.—*Science Monthly.*

WIRE NAILS.—The manufacture of wire nails is an industry that is now receiving quite an impetus in this country. It has not, as yet, reached large proportions, but bids fair to grow rapidly. There are about a half a dozen manufacturers of wire nails now in business, and two or three companies have lately been organized to come in for a share of the trade. By means of automatic machinery, wire nails may be made quite cheaply. In France they are used more than cut nails.

REDUCED PRICE OF CHAINS.—A proprietor of a chain works says that in 1865, when he first commenced making chains, he got over \$1 a pair for trace chains, seven years later 65 cents, and now 35 cents. For coil chains, in 1872, he got 28 cents a pound, against a little over 61 cents now.

The actual cost of making a ton of iron in the Lehigh Valley, Pa., is put down by Mr. McCreat, chemist of the Geological Survey of Pennsylvania, at \$30.35, itemized as follows: Ore, \$9.34; coal, \$5.30; limestone, \$0.77; labor, \$2.33; incidentals and repairs, \$2.64.

SCIENTIFIC PROGRESS.

The Evolution of Mind.

In a lecture on the dawn of mind, delivered at Owens College, Manchester, England, March 28th, by Mr. G. J. Romanes, he claimed that the whole structure of mind took its rise from excitability, or the aptitude to respond to nervous stimulus, which was a characteristic of all matter that was alive. Next to excitability, in an ascending scale, they had the functions of discrimination and conductivity. Discrimination he believed to be a function of all nerve-cells; it was the power to discriminate one stimulus from another, irrespective of the degrees of their mechanical intensity. Conductivity was a function which admitted the possibility of reflex action, and of the co-ordination both of muscles and of ideas. In the faculty of discrimination they had the physical aspect of that which elsewhere was called choice, because choice, if it was analyzed, was merely the power of discriminating between one stimulus and another. With the aid of an elaborate diagram, Mr. Romanes traced what he held to be the various grades in the process of mental evolution from excitability as the root of the mind. The diagram had forty lines or levels. Any given level represented the earliest stage in the development of all the faculties named therein—the animals in which, and the age of the human being at which, they first appeared; also the grade of development at which human intelligence was arrested in idiocy and deaf-mutism. The diagram was not, he said, a mere production of his imagination, but was the result of his study of the subject. At the bottom, on a level with excitability, he placed protoplasm. Reason, he thought, arose out of the powers of perception, for the simplest possible perception involved some act of inference—an act unconsciously performed, perhaps, but performed all the same. Regarding reason in its lowest phase, it must be placed immediately above the association of ideas, because they might regard it as a process of unconscious or deliberate inference, and this occurred in monkeys, dogs and elephants. Next above reason he placed indefinite morality, or the germ of conscience. Indefinite morality was the feeling of dislike at offending those for whom the child or animal having felt an affection. Definite morality was much higher in the scale; it was, in fact, at the top, on a level with man. A child at birth he placed, in this process of mental evolution, on a level with jelly-fish; at five months old, he put the child on a level with pigs, horses and cats; and at nine months, on a level with the anthropoid apes. He could not help feeling that the doctrine of evolution, as a whole, was a somewhat hard doctrine—hard as an answer to the question which must at some time, or in some shape, have occurred to most: "Shall not the Judge of the whole earth do right?" The answer that evolutionists made to that seemed to him to be a hard one, for it said that in the order of nature the race was always to the swift, and the battle, without fail, to the strong. Thus the voice of science proclaimed a new beatitude: "Blessed are the fit, for they shall inherit the earth." This doctrine seemed to constitute might the only right. But if this world was a world of sorrow, struggle, pain and death, at all events, the result, so far, had not been altogether profitless. Whatever the "far off divine event" might be, to which "the whole creation moves," the whole creation, with all its pain, and in all its travail, was certainly moving, and moving in a direction which made, if not for righteousness, certainly for improvement.

Phosphorescence of the Diamond.

Experiments are reported as having been recently made in Paris on the phosphorescent properties of the diamond. This precious stone, says a foreign exchange, has been supposed to be one of a small number of bodies which possessed the property of emitting light after having been exposed to the sun or electric light or submitted to the action of friction. But this interesting fact has, until recently, been hardly more than an apothesis, on account of the difficulty of procuring gems of sufficient size to experiment upon, for the diamonds in laboratories and geological museums were all too small to give satisfactory results. All of the large and well-known diamonds are of too great value to be in the possession of private experimenters: such stones as the Kohinoor, the Regent, the Grand Mogul, the Sancy, &c., are all held by different governments. Recently, however, through the courtesy of M. J. Picard, the head of one of the largest diamond importing houses in Paris, certain French scientists obtained the use of a very large diamond. The stone weighed not less than 92 carats, and is said to be the handsomest one in the possession of any private individual. This diamond, which is valued at \$100,000, is of perfectly pure water and of admirable cutting. The results of the experiments made were as follows: 1. That when exposed for the space of an hour to the rays of the sun and then transferred to a dark chamber, and a sheet of white paper held near it, it omitted light for more than 20 minutes, visibly illuminating the paper. 2. That the same phenomena occurred, but with illuminating power of slightly less intensity, when the diamond was similarly exposed to the electric light, as produced by an arc lamp. 3. That after being rubbed for a

few seconds with a coarse flannel cloth the diamond became decidedly phosphorescent.

IGNITING POINT OF EXPLOSIVE.—The question of the temperature at which various explosive mixtures of gas and air become ignited has recently been carefully investigated by two French chemists, Messrs. Mallard and Le Chatelier, their experiments having been carried out with hydrogen as well as carbon gas mixed with air in different proportions. The temperature was recorded by a pyrometer heated in a Morot melting furnace; the interior of the pyrometer was connected with a gas reservoir and with the air in such a manner that the mixture to be tested could be admitted as soon as the desired temperature had been reached. In order to prevent mistakes, repeated experiments were made at degrees of heat which were purposely fixed a little under or over the point of ignition, as already ascertained. From the results of these tests it was found that a mixture of 70 parts of air and 30 parts of hydrogen gas ignited at a temperature of from 1026 to 1028 F., while the temperature of ignition for a mixture of air and carbon gas in similar proportions varied from 1202 to 1215. Increasing the proportion of carbon gas, it was found that the point of ignition could be further raised to 1337.

PHOSPHORESCENCE FROM ATTRITION.—At a recent meeting of the New York Academy of Sciences, Mr. G. F. Kunz stated that while unpacking some specimens of fluorite from Amelia county, Va., he had noticed the display of phosphorescence, a pale greenish light, by the mutual attrition of the specimens, the same being excited also by the warmth of the hands. By the heat of a candle, this phosphorescence was increased, and, on a red-hot stove, became a deep emerald-green. This led Mr. Kunz to examine fluorite from over a dozen localities, and he found that only chlorophane yielded phosphorescent light by attrition. In Phillips's *Mineralogy*, edition of 1823, a specimen of fluorite, described by Pallas, from Siberia, is mentioned, which yielded light by the warmth of the hand. The fact that attrition will cause phosphorescence, Mr. Kunz considered new, and as the same result was produced by chlorophane from Branchville, Conn., it was looked upon as a new distinguishing characteristic between chlorophane and common fluorite, as petiolite from Bergen Hill is distinguished from the fibrous zeolites and other associated minerals.

MICROSCOPIC EXAMINATION OF WATER.—The detection of micro-organisms in potable waters is of considerable hygienic importance. When they are present, yet in relatively small numbers, their detection is difficult unless they can be concentrated in a small volume, which cannot, of course, be accomplished by evaporation. This may be effected by precipitating them in a precipitate that dissolves readily in acids. Brautlecht makes use of a solution of one part of aluminum sulphate in eight parts of water and one part of hydrochloric acid. He puts five drops of this solution in the water to be tested, then adds three drops of the official aqua ammonia, which precipitates the alumina, and with it any organic matter. This he collects upon a smooth filter, and while still soft scrapes it off with a glass rod and dissolves it in ten drops of acetic acid. In these ten drops are to be found all the micro-organisms previously distributed through a large quantity of water, and this is used for microscopical examination. If necessary they may be stained with a suitable dye.—*Pharm. Zeitung.*

THE COLORADO SCIENTIFIC SOCIETY.—Messrs W. P. Hillebrand and Richard Pearce, of the Colorado Scientific Society, recently made a preliminary communication to the Academy of Natural Sciences of Philadelphia in regard to an interesting group of minerals recently found in Utah, some of them being new to the United States. The minerals found are, enargite and the secondary hydrous arseniates, olivenite and conicalite (Dana's System of min., p. 555), with two amorphous substances corresponding, apparently, to pitticite and chenevixite. The olivenite occurs in small, distinct crystals; the conicalite, in form similar to that from the only locality previously known, in Spain, while its chemical composition is also very near to that of the original mineral, a small amount of copper being replaced by zinc. Jarosite, turgite, and one or two as yet undetermined species, occur sparingly with the above. Mr. Pearce also exhibited pseudo-malachite associated with hubnerite from near Phillipsburg, in Montana.

THE MICROSCOPE IN MEDICAL PRACTICE.—Mr. Andrew Carnegie, of New York, has recognized the growing importance of the microscope in medical practice in the following practical manner: He has made an absolute gift of \$50,000 to Bellevue Hospital Medical College of that city. This sum is to be expended in the erection of a building and an apparatus to be devoted to laboratories for practical work and teaching in medicine. It is the design of Mr. Carnegie to establish a laboratory for the conduct of microscopical investigations, for which this country now affords no facilities adequate with the importance of the work.

PRIZE OFFER.—The Italian government has determined to offer, on the occasion of the opening of the Turin exhibition, a prize of four hundred pounds for the most practicable process for the transmission of electricity.

SAN FRANCISCO:

Saturday Morning, June 14, 1884.

TABLE OF CONTENTS.

EDITORIALS.—Mining and Mechanical Engineers; Encourage the Prospectors; Technical Society of the Pacific Coast; Key-Sighting and Slotting Machine; 397. Passing Events; Bullion Production; Coal in California; The Cœur d'Alene Mines, 400. Atlanta and Rocky Bar; Pneumatic Street Railway; The Rains, 401.

ILLUSTRATIONS.—The Davis Key Senter and Slotting Machine, 197. Atlanta and Rocky Bar, Idaho, 401. Views of Wilmington Harbor, Los Angeles County, Cal., 402.

MECHANICAL PROGRESS.—Improved Method of Producing Steel Plates; Perforated Feed Pipes; Progress in Locomotive Construction; Steel Nails; New Steam Saw; Pointing Steel; Wire Nails; Reduced Price of Chains, 399.

SCIENTIFIC PROGRESS.—The Evolution of Mind; Phosphorescence of the Diamond; Igniting Point of Explosive; Phosphorescence from Attrition; Microscopic Examination of Water; The Colorado Scientific Society; The Microscope in Medical Practice; Prize Offer, 399.

ENGINEERING NOTES.—The Hudson Bay Route; An Elevator Operated by Electricity; Railroad Building at the South; The San Francisco and Oakland Tunnel; Electrical Engineers; Ocean Cables, 403.

USEFUL INFORMATION.—Useful Information; A Remarkable Water Power; Cheap Method of Preserving Fence Posts; Advantages of the Cable Railway; To Obtain a Malagasy Color; Coloring Silk; Asbestos Rope; To Soften Hard Rubber; Paper Instead of Cedar for Lead Pencils; Power Employed in Walking; Metal vs. the Usual Material for Stringed Instruments; To Make Iridescent Glass; Dressing for Leather, 403.

GOOD HEALTH.—“Electrical Medication” Again; Tar Smoke for Diphtheria; Are Baking Powders Unhealthy; Death; Health; To Remove India Ink, 403.

MISCELLANEOUS.—Electric Currents in Mines; Phosphorus in Iron; The Black Hills; Underground Manhole, 398. Wilmington Harbor; Prevention of Accidents in Mines, 402.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 404-5.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board, Notices of Meetings, Assessments, Dividends and Bullion Shipments, 408.

Business Announcements.

The “Dug” Bucket.—Iron Chad Mfg Co., New York.
Water Wheels in Art. Pottery, Nevada City, Cal.
Assessment Notice.—Gould & Curry M. Co., S. F.

See Advertising Columns.

Passing Events.

The copious rains of the past few days are a matter of wonderment to Californians who never expect any such downpour at this season. They have done considerable damage, which is much to be deplored.

In the sinking of the winze to the 3200 ft. level of the Mexican mine, on the Comstock this week, the greatest underground depth on this continent has been reached. The miners work at great disadvantage at these depths, but still persevere on their explorations.

They have been striking some rich quartz in the Cœur d'Alene mining region, Idaho, and it is hoped that a good quartz country will be developed in addition to the placer mines.

The trial of a new system of street car propulsion in our city, elsewhere referred to, is a matter of importance to the community, since air is to displace horse-power on two of our local roads. Interesting problems will be solved, moreover, from an opportunity to compare the cable, horse and compressed air systems of car propulsion, side by side.

EDWARD BADLAM, the sixteen-year-old son of Alexander Badlam, has received a United States patent for an improved steam boiler which he invented. The youth has also several other applications for patents on file at the Patent Office.

Bullion Production.

The different bullion producing States and Territories west of the Rocky mountains have none of them any official whose duty it is to collect the statistics of bullion production. This is mainly left to the newspapers, and we have reports more or less correct. The Government, however, does collect the statistics, but not in a perfectly satisfactory manner. The Department of Mineral Statistics of the U. S. Geological Survey attends to all the statistics of production except those of gold and silver. The Director of the U. S. Mint collects those and publishes them in his annual report. Our main dependence has always been placed on the figures collected by Mr. Valentine, General Superintendent of Wells, Fargo & Co.'s Banking and Express Co., and his statistics have usually been regarded as more accurate than those collected by the Government employees. Most of the data on the subject is based on the figures yearly presented by Mr. Valentine.

It is noteworthy that the Valentine statistics always show a larger yield than those compiled by the Mint Director. The express company enumerates all that passes through their hands in transportation, adding a percentage for the amount carried by private hands. The Mint takes its deposits, crediting them to the region from which they came. The annual report of the Mint Director has just been issued, and a summary of the bullion product has been telegraphed here in advance of the receipt of the book. The figures are for the calendar year 1883, and the total yield of gold is set at \$24,000,000, and silver (at its coining rate) \$46,105,000. We have tabulated the statement, placing the States and Territories in the table in their rank as bullion producers:

State or Territory.	Gold.	Silver.	Totals.
Colorado.....	\$410,000	\$17,300,000	\$17,710,000
California.....	14,120,000	1,460,000	15,580,000
Nevada.....	2,500,000	5,430,000	7,930,000
Montana.....	1,800,000	6,000,000	7,800,000
Arizona.....	950,000	5,200,000	4,150,000
Utah.....	140,000	5,630,000	5,770,000
Idaho.....	1,400,000	2,100,000	3,500,000
Dakota.....	3,200,000	150,000	3,350,000
New Mexico.....	280,000	2,845,000	3,125,000
Totals.....	\$24,000,000	\$46,105,000	\$70,105,000

The remainder of the total was produced in Alaska, Oregon, Georgia, and North Carolina; and the aggregate shows a falling off from the previous year of \$2,500,000 in gold and \$600,000 in silver.

It will be seen that according to these figures Colorado still holds first place in the list of bullion producers and first place as a silver producer. California still holds first place as a gold producer and second position in rank as bullion producer. This is the same result as last years figures showed. Nevada still holds third place as bullion producer, and second place in silver production. The table is very suggestive, giving as it does the results of work done in the different mining regions. It does not follow, it will be seen, that where there is the most talk there is the most work. While our mining industry has been depressed in California we have kept the same relative position we have had for many years, as compared with other regions.

Coal in California.

Now that so many manufacturing establishments are running in our midst, the question of our coal supply is a very important one indeed. Our own coal supply in the state is from the Mt. Diablo mines, but it is not liked for domestic purposes, being mainly used for making steam. The Coos Bay coal field in Oregon gives us a large quantity as does the mining region of Washington Territory, and British Columbia. Vancouver's Island shipments last year were 300,000 tons and Washington Territory shipped 164,986 tons. The Mt. Diablo mines yielded in 1883, 76,162 tons. From Tacoma, W. T., we received last year 137,420 tons. We get coal also from Australia, Great Britain, and the Atlantic Coast. When we have a heavy crop of grain, we get a great deal of foreign coal, the ships coming here for grain, bringing the coal. With a short crop our foreign coal imports always fall off. The statements, given below, will serve to indicate the consumption of the several varieties of coal at San Francisco. The principal sources of supply, are from Mt. Diablo, in the immediate vicinity; from Coos Bay and Renton in Oregon, and the ports in Washington Territory; from Vancouver's Island, from Australia and Great

Britain, as also Cumberland and Anthracite from the Atlantic Coast.

Qualities.	Tons, 1883.
Foreign—Australia.....	150,316
English, Welsh and Scotch.....	155,192
Vancouver.....	117,822
Eastern—Anthracite.....	26,725
Cumberland.....	16,555
Domestic—Mount Diablo.....	76,162
Coos Bay and Renton.....	24,525
Seattle, W. T.....	164,986
Tacoma, W. T.....	137,420
Total.....	860,615

Frederick E. Seward, of New York, issues each year a little work on “The Coal Trade,” giving statistics from all over the world. We received the book last week, and compile from it some statistic of local interest. The following table shows total receipts of coal at San Francisco for the past three years:

Qualities.	Tons, 1881.	Tons, 1882.	Tons, 1883.
Foreign—Australia.....	126,296	158,901	150,316
English, Welsh and Scotch.....	231,313	188,771	155,192
Vancouver.....	158,022	157,762	117,822
Eastern—Anthracite.....	13,697	24,996	26,725
Cumberland.....	24,982	14,860	16,555
Domestic—Mount Diablo.....	103,055	113,255	77,162
Coos Bay and Renton.....	20,000	14,533	24,525
Seattle, W. T.....	152,893	154,611	164,986
Tacoma, W. T.....	54,627	137,420

The production of coal in the United States for the year 1883 is as follows:

States.	Tons.	States.	Tons.
Alabama.....	1,400,000	Montana.....	50,000
Arkansas.....	75,000	New Mexico.....	250,000
California.....	200,000	Ohio.....	8,220,429
Colorado.....	1,000,000	Oregon.....	60,000
Dakota.....	50,000	Penn., anthracite.....	31,793,027
Georgia.....	200,000	Penn., bituminous.....	24,000,000
Idaho.....	10,000	Tennessee.....	1,000,000
Illinois.....	10,508,791	Texas.....	100,000
Indiana.....	2,400,000	Utah.....	250,000
Indian Territory.....	175,000	Virginia.....	225,000
Iowa.....	3,881,300	Washington Ter.....	200,000
Kansas.....	850,000	West Virginia.....	2,250,000
Kentucky.....	1,650,000	Wyoming Ter.....	700,000
Maryland.....	2,306,172		
Michigan.....	135,000	Total.....	96,159,719
Missouri.....	2,250,000		

Below will be found the analyses of some coals found in British Columbia:

PLACE.	Thickness of Seam in feet.	Water.	Carbon.	Fixed Carbon.	Ash.	Sulphur.
Queen Charlotte Island:						
Anthracite coal.....	3 to 4	1.60	5.02	85.75	6.69	0.80
Vancouver's Island:						
Newcastle coal.....	3 to 4	35.49	52.57	11.04
Wellington (Dunsuir seam).....	4 to 6	34.70	55.50	9.80
Exmouth River (Comox).....	4 to 5	32.51	57.73	14.44
Trent.....	3 to 4	52.28	56.76	7.32
Union Mine.....	5 to 10	1.70	27.17	68.27	2.86
Baynes Sound Mine.....	5 to 6	49.56	54.70	5.75
Mainland, Brit. Columbia:						
Nicola River.....	15 to 3	21.51	74.58	3.91
Hut Creek.....	42 to 46	8.60	35.51	46.84	9.05
Chilliwack.....	5	35.73	63.86	.41
United States:						
Seattle coal, Puget Sound.....	11 to 60	35.49	45.97	6.44

We find the following analyses of Coos Bay and Astoria coals compared with Nanaimo and Bellingham Bay:

	Astoria Coals.	Coos Bay.	Nanaimo.	Bellingham Bay.
Water.....	2.56	20.60	2.98	8.39
Volatile matter.....	46.29	32.30	32.16	33.26
Fixed carbon.....	48.41	41.08	46.41	45.69
Ash.....	2.74	5.34	18.55	12.66

The coal production of the world in 1882, from the best sources, was as follows:

	Square Miles of Coal Area.	Tons.
Great Britain.....	11,900	156,490,977
United States.....	192,000	86,849,846
Germany.....	1,770	65,333,925
France.....	2,086	20,803,332
Belgium.....	510	17,590,853
Austria.....	1,800	19,000,000
Russia.....	30,000	3,600,000
Spain.....	3,501	900,000
Novia Scotia.....	300	1,365,811
Australia.....	24,840	2,100,232
India.....	2,000	1,000,000
Japan.....	5,000	800,000
Vancouver's Island.....	390	335,000
New Zealand.....	50,000
Chile.....	50,000
Sweden.....	90,000
Italy.....	220,000
Total.....	379,718,162

With regard to wages paid for digging coal in the United States, it may be stated that the highest price is paid at Lerdo, Texas, an 18-inch coal being \$1.50 per ton. The lowest figure is at Latrobe, Pa., 26 cents per ton.

Customs officers have been instructed to be careful to confine the issue of certificates to Chinese laborers who depart directly for foreign ports, and to refrain from issuing them to laborers who intend to proceed to China or any other foreign port via some other port in the United States, or to Chinamen who are not laborers.

S. W. TALMAGE, of Michigan, has issued his annual estimate of the spring and winter wheat crops. They are as follows: Spring wheat—Minnesota, Nebraska, Iowa, Dakota and Wisconsin—total, 141,000,000 bushels; winter wheat, in all other States and Territories, 375,000,000 bushels, or a grand total of 516,000,000 bushels.

MILLER's objection prevented Glascock from getting through the House his bill for a public building at Sacramento.

The Cœur d'Alene Mines.

We had a conversation this week with a gentleman connected with one of the large foundries in this city who has just returned from a visit to the Cœur d'Alene mines, in Idaho, and obtained from him some points of general interest. To get to the mines from here he took the steamer to Portland, Oregon, and then went on the Oregon railroad to Wallula junction, where he took the Northern Pacific for Rathdrum. From that station he went by stage 12 miles to Post Cœur d'Alene and across Lake Cœur d'Alene, 60 miles, on the steamer. On this fine new steamer there are good accommodations, and the passenger may remain aboard all night if he desires. The scenery around the lake our informant pronounces finer than that at Lake Tahoe. He took the stage again for 18 miles to Jackass Prairie, and then 20 miles across the mountains on a Cayuse pony to Eagle.

It is stated that there are about 5,000 people in the mines, but it is difficult to decide on this, so many are scattered through the mountains prospecting. There are a good many from the east and Colorado, huying up claims—Leadville men being particularly active in this. There are comparatively few men from California.

The gravel in the mines, our informant says ranges from 3 to 30 feet in depth, but mainly deep, and the gold is nearly all on the bedrock. The gold is coarse and heavy, and is worth from \$17 to \$18 per ounce. One man buys most all the gold and ships it to the government assay office at Helena, Montana. The bullion shipments attract therefore little attention, individuals shipping little.

In prospecting, the men find places where the bedrock is not deep, but in many cases they go down through the deep gravel. The “Widow's” and “Dream Gulch” claims are the principal ones, though there are many others of less importance being worked. The Dream Gulch, running a short time, cleaned up an average of 90 ounces a day. The gulch is easily worked. They use a 60-inch head through an ordinary 6-inch canvas hose with brass nozzle, like hydraulicking, and have about 150 feet of sluices. The gold being heavy, is easily caught in a short string of sluices. The gravel they are washing is about 20 feet deep, but nearly all the gold is on the bedrock. They have even gone over the bedrock two or three times, and when our informant left they were scraping the soft bedrock the third time.

An offer of \$85,000 has been made for the claim. They have 2,640 feet in the mine. They had worked one twenty-sixth in length without touching the sides, and had taken out \$14,000 after working a short time. In one place, measuring 8x12, on the bedrock, they took out 62½ ounces of gold.

Very few of the claims are fitted up for good work. The two mentioned and one other are the only ones at all ready for work. The Earp Brothers, formerly of Arizona, have a claim well rigged up with flume, overshot wheel and Chinese pump, like an old-fashioned California placer mine. A short flume serves to bring in the water, and they have fall enough to their ground to have no trouble.

There is considerable water all through the claims, and the little valley is soaked, but later on there will not be so much trouble from this source, but at both Eagle and Murray the miners will have to dig long bedrock drains or rig pumps, in order to work their claims properly. Those in the gulches, like the “Dream,” have fall enough to get rid of the water easily, but at other places they will be compelled to pump more or less to keep the claims clear.

A great drawback is the lack of roads, of which there are none between the camps and and none nearer than 20 miles. All provisions have to be packed in, and the lumber has to be whip-sawed. There are three sawmills near Eagle, yet all the lumber used at Murray is whip-sawed. The dwellings are of log or canvas. The country is thickly wooded and hard to travel in.

There are several good quartz prospects, but as yet there is no machinery. One big prospect is the Mother Lode. A slab of quartz shows above the water on Pritchard Creek, which the owners say shows \$10,000 in gold, but others say the slab carries more likely, \$1,500 or \$2,000. They have not taken it out, desiring rather to sell. The quartz shows across the creek, and

they want \$100,000 for the claim. The first excitement brought town lots up to exorbitant prices, but there is plenty of land and nothing to warrant it. Many persons have left Eagle and gone to Murray, which will be, if it is not now, the main center of the region, most of the best mines being in the vicinity. The great difficulty now is that the miners now there, have no money. They came in early and exhausted their resources. They need money to open their claims. They own the claims, but that is all. It is the opinion of our informant, that though the region is rich beyond question, it will not be developed as it warrants until outsiders come in, buy, and work the claims, with the exception of the few well-known rich ones. Experienced men there pronounce the country a rich one and with great future possibilities both in placer and quartz mines. There are some very rich quartz prospects at Evolution and on Beaver Creek.

There is now talk of building a road between Eagle and Murray. If they do, it will help the whole country. They will get in their supplies and necessary lumber cheaply, by wagons, in that case. Provisions are now high, and it is of course impossible to "pack" in lumber. There is also a move to build a road in from Trout Creek, which will give then a road 32 miles from the railroad track.

Atlanta and Rocky Bar.

In concluding the series of articles on Idaho mining districts, with the maps from the report of the Director of the United States Mint, we present a sketch showing the surroundings of Atlanta and Rocky Bar.

Rocky Bar is situated in the western part of Alturas county, on Bear Creek, a tributary of the South Boise river. The mines here are all gold mines, the ore being either free milling or rich sulphurets. The chief mines which have been worked during the past year are the Idaho and Vishnu and the Ada Ellmore. The Idaho and Vishnu rank with the best gold mines of the Territory, but until lately have not been systematically worked. The owners had leased them to miners of limited means, who extracted the ore without keeping development work ahead, and left the mine in bad condition.

During the past year the property finally changed hands, and under an able and experienced management work has been vigorously and systematically pushed forward. The Ada Ellmore has long been a large producer of gold, and since it was first opened has produced over \$1,000,000. It is a true fissure vein, of free-gold bearing ore, 4 feet wide, which will probably average \$60 to the ton.

There are a number of other mines in this district which, under careful, intelligent, and economical management, could be made to yield large returns and give a future of importance and influence to a section of country which has not hitherto attracted the attention its importance demands. Fifteen miles north of Rocky Bar is Atlanta, on the Middle Boise river. The formation in this district is granite, with dikes of syenite and varieties of porphyry. The veins carry both gold and silver, and run nearly east and west. The principal ledge is the Atlanta, on Atlanta Hill, which has been traced for a distance of nearly 2 miles, and from 30 to 80 feet in width. In this there are several veins carrying ruby silver, silver glance, black sulphuret, native silver, and free gold. The chief mines on this lode are the Buffalo, Monarch, Last Chance and Leonora. The Buffalo has continued its operations steadily. Since 1874 it has produced an average of \$100,000. The Monarch is an old mine, having been located 20 years ago. The property consists of 1,600 feet, running east from the center of Quartz Gulch. The ore was formerly worked with a wet-crushing, 10-stamp mill, but the result was unsatisfactory, and the company owning the mine leased it until 1878. Since that time it has been operated by the company, the lessees having found the mine so profitable that the company refused to renew the lease. The Last Chance mine is the property of the Atlanta Hill Gold Mining Company. The ore is free milling, and runs from a 3 foot vein.

THE President has sent to the Senate a message suggesting the propriety of Congress appropriating \$588,000 for the purpose of making a complete and harmonious exhibition on behalf of the Government at New Orleans. It was referred to the Committee on Appropriations.

Pneumatic Street Railway.

There has just been completed at the Risdon Iron Works, in this city, an experimental car to be run with compressed air by a new system, a trial of which was made last week. The subject is one of great interest, more especially as the system will be tried where close comparisons can be made between it and both cable and horse-car as to relative economy. In the new plan there is a storage and charging pipe which carries the air below the surface of the road-bed all along the route, contiguous to the track. Through a system of valves attached to this pipe, closely set together within the track, the pipe may be tapped and the receivers replenished at any and all points on the route. In this way the system is so arranged that the car is never removed from its source of supply, and has no determined distance to

be run as an open car, after the style of the cable road dummies, and the air receivers are placed under the seats. From these receivers, which are connected by a pipe, a hose connection is made which terminates in a metal nozzle, in the end of which is fitted a valve to make connection with the service pipe, as described hereafter.

The main service pipe is placed underground, near the track, and is large enough to have in itself storage capacity sufficient to insure that the drawing off of each charge for the motors will not greatly decrease the pressure. It is thought that a pipe of five or six inches diameter will do for roads running cars five minutes apart, whilst it should never be less than four inches in diameter.

This main pipe is provided with right angle branches, say every 300 feet more or less, which lead to the center of the track and terminate in

reducing valves. It is expected that the new cars can run on the Howard and Mission street routes where they are expected to be placed, at a pressure of 30 pounds, but this can be increased at will by means of suitable mechanism. When the conductor strikes the bell for a passenger to get on or off, the engineer stops at just where the next valve of the supply pipe is located or within a few feet thereof. These valves are placed at street crossings generally. The engineer then takes down his feeding nozzle and inserts it into the hole in the street and connects. The air rushes through the nozzle and fills the reservoir until the bell sounds to start, when the nozzle is taken up and replaced on its stand. The engineer need not wait to get the first few pounds of pressure but may start with such pressure as he has obtained. In this way no unnecessary delay occurs.

The car or motor need not be required to travel over six or eight blocks, or even a less distance, where stops are frequent. The valves may be placed at crossings or even every hundred feet if necessary. It is desirable to be able to refill the receiver at every stop to have great pressure when starting. Several suggestions have been made to operate street railroads with compressed air carried near the track, but none have included within their scope the system here proposed, which is the invention of Mr. George Parry of this city. In this system the maximum weight of the load and contingencies of the trip do not control, but have only the effect of limiting the distance the motor will be capable of traveling without having recourse to the supply pipe, constantly at hand. In fact those stoppages which are of necessity, caused by taking or of leaving passengers are the only ones necessary to make, it being calculated that these will be ample in most cases to give the required opportunity to replenish the receiver.

In running on this system they get over the great loss of power required to move a cable. On the cable roads 68 per cent of the power is necessary to drive the cable alone without counting cars or passengers. Then again it is different from steam dummies or locomotives in this, there is only one central fire for the compressing machinery, instead of separate fires, boilers, etc., for each machine. They expect to utilize 50 per cent of the useful effect of the compressed air. One engine supplies all the cars. These cars are expected to go up a grade of one in fifteen.

The experimental trial of the system made last week proved very satisfactory to the promoters. The car ran with 100 pounds pressure for three-quarters of a mile one trip, and seven-eighths of a mile the second trip. The car weighed about 3½ tons and the passengers 2½ tons. The highest speed attained was 16 miles per hour, and the car went up a grade of one in thirty-seven at 8 miles per hour. The connecting valve worked satisfactorily. It is probable that this system will be adopted by the Howard and Mission street car lines. They propose to erect one engine house on the corner of Howard and Tenth streets, which will serve to compress air for both roads, each paying its proportion of expenses. The details have not, however, been arranged by the companies.

The Rains.

June rains have been phenomenally heavy this year. It is usual to have a nice sprinkle, but a drenching rain which sends water pouring down the hillsides and makes mud of all the summer dust is something altogether exceptional. It will furnish another peg on which to hang the popular theory that the climate is changing and that we may lose our dry summers after all. The trouble with such claims is that we have in fact a very small cycle of experience to figure on in California, and we are apt to be surprised at things which perhaps have happened time and time again just before the year with which our records begin.

These heavy June rains are not acceptable as a rule, though it is likely that their evil effects are sometimes exaggerated. This year they have spoiled quite a large amount of hay, but they have also prolonged the pasturage season by giving new vigor to the grasses and sprouting new seeds.

WILLIAM E. SHARON, a nephew of ex-Senator Sharon, has been appointed Superintendent of the Yellow Jacket mine, to fill the vacancy caused by the resignation of Charles Forman,

ATLANTA AND ROCKY BAR, IDAHO.

travel with each charge, so that it may have a minimum capacity as to storage room and pressure of air instead of the maximum, as when the length of the journey to the charge is absolute and fixed.

Compressed air motors have been run a definite distance without replenishing, as from end to end of a route and back, and suggestions have been made to run from station to station, using a pipe connection between, but in all cases provision has had to be made for carrying the heaviest possible load of passengers under the most adverse circumstances likely to occur, such as those arising from very frequent stoppages, bad condition of the track, accidental delays, etc. The definite points could not be passed without re-filling the receivers, and either the engineer had to go or the motor itself had to be taken to the station off from the main line in the act of re-filling, this system of operation leading to all the difficulties which have heretofore surrounded the use of compressed air as a motive power for street roads. No practical system has been put in use so far by which the motor could be re-supplied with air at any and all points on the route.

The motor which has just been tried is con-

structed as an open car, after the style of the cable road dummies, and the air receivers are placed under the seats. From these receivers, which are connected by a pipe, a hose connection is made which terminates in a metal nozzle, in the end of which is fitted a valve to make connection with the service pipe, as described hereafter. The main service pipe is placed underground, near the track, and is large enough to have in itself storage capacity sufficient to insure that the drawing off of each charge for the motors will not greatly decrease the pressure. It is thought that a pipe of five or six inches diameter will do for roads running cars five minutes apart, whilst it should never be less than four inches in diameter. This main pipe is provided with right angle branches, say every 300 feet more or less, which lead to the center of the track and terminate in

reducing valves. It is expected that the new cars can run on the Howard and Mission street routes where they are expected to be placed, at a pressure of 30 pounds, but this can be increased at will by means of suitable mechanism. When the conductor strikes the bell for a passenger to get on or off, the engineer stops at just where the next valve of the supply pipe is located or within a few feet thereof. These valves are placed at street crossings generally. The engineer then takes down his feeding nozzle and inserts it into the hole in the street and connects. The air rushes through the nozzle and fills the reservoir until the bell sounds to start, when the nozzle is taken up and replaced on its stand. The engineer need not wait to get the first few pounds of pressure but may start with such pressure as he has obtained. In this way no unnecessary delay occurs.

Wilmington Harbor.

One of the most important works ever done by the government on this coast was the improvement of Wilmington harbor, near Point San Pedro. This was one of the first shipping points ever utilized on this coast, and many will remember the description by Dana in his famous "Two Years Before the Mast," where he tells how they loaded hides in the old brig near Deadman's Island. In those days when southeasters came the vessels had to try and ride them out, or else stand off to sea. Now, however, the government has formed a safe and capacious harbor which is the shipping port of Los Angeles, the chief city of Southern California, which is situated twenty-one miles inland.

The harbor was formerly called San Pedro bay. Before the U. S. engineers took hold of the harbor the bar was very shoal and even the small steamer carrying passengers from the ocean steamers at the moorings in the roadstead

wells, and been, in fact the presiding genius of the place. He has been for very many years in the freighting and transportation business at San Pedro.

Wilmington harbor was made a port of entry in June, 1882. It has steadily increased in importance as a shipping point since the Government began improving it. Between \$600,000 and \$700,000 have been appropriated by Congress for the work, but it has proved a fortunate thing. The city of Los Angeles is the metropolis and railroad center of Southern California, is 500 miles distant from San Francisco, and is the largest city south of that point. Its unrivaled resources, the unlimited market for its diversified products, and superb facilities by rail and sea for the transportation thereof, attest to its superior advantages for becoming a great commercial and maritime metropolis. The increasing competition for the trade of the southwest, caused by new lines of railroads, aroused the Southern Pacific managers to the necessity of establishing a first-class harbor in Southern California for the transaction of their business, and, after a thorough examination, Wilmington was selected for that purpose. The railroad has been extended from thence to deep water, a dis-

Prevention of Accidents in Mines.

The following essay, by William Davison, a deputy in the Hedley Hill Colliery, obtained the second prize in the Peases' West Institute competition, and was published in the *Colliery Guardian*:

Explosions.

(1.) To keep all winning places and exploring drifts well in advance of the general workings of the mine, and if of a gaseous nature, to have boreholes in front and occasionally in the roof and floor in the neighborhood of faults, etc., as a precaution against any sudden outbursts. The places being well ahead, time would thus be secured to deal with the danger before being come up to by the rest of the workings. Eruptions of gas, to a large extent, may thus be met successfully, provided such places are worked by the exclusive use of the safety lamp, and the air from such places never on any account allowed to pass into the rest of the working places, its probability to ignition being reduced according to the number of lamps it has to pass. (2.) Such mines to be formed into districts, en-

thus be able to bear an enormous strain, or if preferable, they could be built of iron, but however they are built they should be able to resist an explosion from either side, and should not be depended on unless able to do so. Air will go the most direct route it can get from the shaft, and that ought according to theory (even in the occurrence of a blast) to be through the portion of a mine it is intended to supply with air, consequently the ventilation should depend on nothing liable to be disorganized by a blast. (5) The application of fans for the purpose of ventilation, as being decidedly safer than furnace ventilation. Two fans would be better than one, each to work a stated period alternately, the fan not going to have its connection with the pit broken off, so that if the working fan was in any way injured by explosion or accident, the connection between the mine and the other fan could at once be established; or if a furnace was used it should not be supplied with the return current, which should be conducted by dump drifts beyond the reach of fire, and no fear of the return coming in conjunction with it. (6.) A thorough knowledge of air ventilation and gases should be acquired by all underground officials, so as to immediate-

VIEWS OF WILMINGTON HARBOR, LOS ANGELES COUNTY, CAL.

up to Wilmington could not cross it at less than half tide. The entire business of the place was done by lightering; coasting vessels and steamers can now enter the harbor. The lumber vessels and other freighters go inside the walls up to the wharves, where ship and ear come together. The harbor has a total wharf frontage of four miles, one mile of which is completely occupied by the demands of its large and rapidly increasing business. The average depth of water along these wharves is 18 feet at mean low tide. The rise of the tide is 7 feet and 2 inches, thus giving a depth of over 25 feet at high water, and with the additional improvements projected by the Government, a channel will be secured at the entrance of the harbor of from 300 to 400 feet wide, with a depth of 19 feet at mean high water, and 23 feet at high tides, whereby vessels of the largest tonnage can reach the wharves.

The Government engineers constructed a breakwater 6,700 feet long, part wood and part stone, from Rattlesnake Island to Deadman's Island. On the inner side, and running nearly parallel with the large breakwater, is a smaller one, intended to direct the current.

The distance between San Pedro and Wilmington—3 miles—has been piled in durable fashion by the southern Pacific R. R. Co. The railroad company's wharf is 3,000 feet long. General Banning's ballast wharf is 200 feet long. The Pacific Coast Steamship Co. has a 200-foot wharf. The Los Angeles and Humboldt Lumber Co. have 300 feet of wharf also. The dredging operations have resulted in deepening the channel so steamers can land. The town of San Pedro is a growing one. Wilmington is a small town at the head of navigation. General Phineas Banning, who has made his home there for many years, is well known by visitors to Southern California. He has built and run steamboats, had tugs and lighters, built wharves and warehouses, dug

tance of three miles, and immense wharves have been constructed, as already stated.

The railroad from Wilmington and Los Angeles via Yuma and the Sunset route to New Orleans, forms the shortest transcontinental line from ocean to ocean, and through the most eligible pass, (that of San Geronimo) geographically, in the whole range of the Sierras.

In addition to the transcontinental routes, the various branches of the Southern Pacific to Wilmington, Santa Ana and Santa Monica, and a projected extension from Santa Ana to San Diego, also a projected coast road from San Luis Obispo south to a connection with the Southern Pacific at Newhall, and the assured speedy extension of the Utah Southern to Los Angeles and Wilmington, justify the assertion that her magnificent railroad and maritime facilities, added to her splendid resources, entitle Los Angeles to a rank among the prominent cities of the United States.

The engravings given herewith show in a sketchy style, from drawings by Ed. L. Merritt, some of twenty-six prominent features of the harbor. The lighthouse stands on Point Firmin, on the west side of the bay. Deadman's plane forms the point of the east side. The splendid steamers of the Pacific Coast Steamship Company run regularly to this harbor, carrying passengers and freight, and it is a very pleasant trip to or from this city along the coast, the accommodations being good. To those who want a short sea voyage, there is no pleasanter trip.

They have begun shipping ore from the Hale & Norcross mine to the Mexican mills on the Carson river. A lot of 1,000 tons will be sent and piled up ready for crushing as soon as the present mill run is completed.

The Puget Sound mine produced 22,240 tons of coal last month.

tirely independent of each other for their supply of air, the intake to be in the center and returns at each extremity of district, or the intake in the center and returns immediately on each side adjoining the intake. The latter plan is preferable. In the event of the first or second place on either side becoming foul, a temporary overcast of air-boxes could be adopted to conduct the air from such place direct into the return, thus preventing the danger of causing the rest of the places being made foul also. It would facilitate ventilation by increasing the area of airways, besides preventing the air from polluting more than its own district. Moreover, if an explosion should occur, it would thus be confined to the limits of each district, instead of circulating through the entire pit. (3.) Where broken is following up the whole workings, regulators should be placed at some point where most applicable between the broken and whole workings, and not at the entrance of the intake or return currents. This would prevent any influx of gas from falls in the goaf overpowering the ventilation and backing into the whole workings. Regulating doors should be securely locked. (4.) The ventilation should depend on as few doors as possible, as I consider they are weak points in a mine, but where they are requisite should be self acting, and in situations of importance duplicate ones should be set back in the coal or hung from the roof, for if the doors in use were injured or blown away by an explosion, the duplicate ones could be closed and the ventilation restored, and thus carry away the afterdamp, which is more dangerous to life than the explosion. All stoppings should be strongly built, and of the form of an ellipse, the space between the walls filled up with rubbish; stoppings so built will be better able to resist the force of an explosion than straight walls merely supported by stowing. Air crossings should be built in the form of a semi-circle, and strongly built they will

ly detect any tendency of the air becoming explosive, but speaking as to large and sudden outbursts of gas, it is a question whether any amount of ventilation would prevent an explosion, for, as I take it, the more vigorous the air current the greater chance of a blast, owing to the mixture being more rapidly and extensively formed. Coal dust is a source of danger in mines by its being mixed and carried by the ventilation; it is difficult to effectually deal with it. The use of water damps the air, renders the floor of the mine soft, increases friction, and thus elogs the ventilation. I think the use of salt would be better than water, as by being sprinkled on the floor the moist nature would tend to lay the dust. Combustion, spontaneously, may arise from iron pyrites; phosphureted hydrogen gas will fire spontaneously in air; all substances like these should be sent out of the pit. Brattice cloth should be hung so that the larger space will be for the ingoing, and the lesser for the outgoing current in working places. (7.) For blasting purposes I would advocate the use of the lime cartridge, and the prohibition of powder where safety lamps are in use as previously alluded to; but where it is used, it should be so placed in the line of least resistance, that as little flame as possible will proceed from the drill-hole, to be fired with fuse or detonation machine, so as to gain time for clearance, not to be fired more than one hole at a time and to have reliable men for the work, who should give a proper warning before firing, in case of persons approaching unseen, or in working places meeting each other, or in proximity to other men. (8.) By the exclusive use of safety lamps, for it is greatly on these that the safety of a mine depends.

PRESIDENT RED of the University of California has received a letter of acceptance of the Mills chair of mental and moral philosophy by G. A. Howison, of Wellesley, Mass.

ENGINEERING NOTES.

The Hudson Bay Route.

The opening up of a great traffic route from Manitoba to Europe, by rail to Hudson Bay and thence by steamers, is still agitated with much persistency. A committee of the Manitoba Assembly have been investigating the matter, and among other inducements for the establishment of the route they cite the following: The committee find that in Manitoba, and the States of Minnesota and Dakota, the grain crops of 1882 amounted to upwards of 80,000,000 bushels. One railway alone (the St. P., M. & M. R.) carried southward 13,087,120 bushels of wheat, and 379,010 barrels of flour during the year ending the 30th of June, 1883, and it is safe to assume that had the outlet via Hudson Bay existed, at least one-half of this produce would have followed that channel to the seaboard.

The committee feels justified in assuring that this route would be extensively availed of by the shippers of this country and the neighboring States of America, in consequence of the fact that the distance from Winnipeg to Liverpool via Hudson Bay is 570 miles less than from Winnipeg to Liverpool via Montreal and the Straits of Belle Isle, and 770 miles nearer than via Montreal and Cape Race, while it is 1,032 miles nearer than by way of New York. By sea, Churchill Harbor is 64 miles nearer to Liverpool than is Montreal; and 114 miles nearer than is New York.

Not only is the all-rail route much shorter than by any other line, but nature has provided water ways from the head of navigation of the Red river to the foot of Lake Winnipeg, which can be utilized for over six months in each year, thus reducing the length of railway line to reach Hudson Bay, to within 100 miles.

The committee expresses the opinion that a railway to Hudson Bay will prove a successful and remunerative undertaking, and are satisfied that such an outlet will do more to stimulate production in that province and the Northwest generally than any other enterprise.

AN ELEVATOR OPERATED BY ELECTRICITY. Electricity seems to be slowly, but surely working, its way into practical utility as a motor. The latest item in this direction is its application as a motive power to an elevator in a Spruce street (New York) store.

The building is six stories high, and the elevator is in constant use throughout the day. Loads of 2,000 pounds are often put on the carriage and moved without difficulty. The power is derived from a station two blocks away, and is carried by wires over housetops. A switch on the ground floor connects or disconnects the current, and the movements of the elevator are controlled as in the application of ordinary power. The service is said to cost less than when done by steam, and if this is true the Daft Company sees opening before it a limitless business opportunity. A house in Beekman street is putting in machinery for an electric elevator which will be required to carry up loads of more than two tons. It is urged that large concerns will ultimately set up dynamos of their own for elevator service by day and lighting purposes by night.

RAILROAD BUILDING AT THE SOUTH.—The large introduction of manufacturing industry at the South has very naturally brought about a corresponding activity in railroad building to meet the increased demand for local traffic and for the more extended development of her timber and mineral lands. Many of the finest and most valuable portions of the country are comparatively unavailable on account of lack of transportation facilities, and it is for the interest of every farmer and producer to aid so far as possible, in their construction instead of opposing and driving them away, and thus building up a few favored and sensible localities at the expense of the rest.

THE SAN FRANCISCO AND OAKLAND TUNNEL.—In reply to a query, we would state that Senator Miller introduced a bill into the United States Senate on the 18th of January last granting the right of way to Henry Anderson, his associates and assignees, for the construction of a submarine tunnel between San Francisco and Oakland. The bill gives Anderson the right to select the location of a tunnel and construct three air shafts. He is to have two years in which to commence work. The right is reserved to the Government to transport soldiers, sailors and officers, as well as stores, free of charge, and also to place therein telegraph and telephone wires.

ELECTRICAL ENGINEERS.—The "American Institute of Electrical Engineers" is the name of a new society recently organized in New York somewhat after the models of the three principal engineering societies now in existence in this country, and to advance in a general way the interests of theoretical and applied electricity. That there is an actual demand for an institution of this kind has unquestionably been felt for some time.

OCEAN CABLES.—It is not generally known, but is said to be a fact nevertheless, that out of the nine cables that now stretch from continent to continent under the Atlantic, only three are in working order, and that of these three only one works one way.

USEFUL INFORMATION.

Useful Information.

The following figures are worth remembering, as they will save a great deal of calculation and give approximately accurate results with a minimum of labor:

A cord of stone, three bushels of lime and a cubic yard of sand will lay one hundred cubic feet of wall.

Five courses of brick will lay one foot in height on a chimney. Nine bricks in a course will make a fine eight inches wide and twenty inches long; and eight bricks in a course will make a fine eight inches wide and sixteen inches long.

Eight bushels of good lime, sixteen bushels of sand and one bushel of hair will make enough mortar to plaster one hundred square yards.

One fifth more siding and flooring is needed than the number of square feet of surface to be covered because of the lap in the siding and matching of the floor.

One thousand laths will cover seventy yards of surface, and eleven pounds of lath nails will nail them on.

One thousand shingles laid four inches to the weather will cover one hundred square feet of surface; five pounds of shingle nails will fasten them on.

A REMARKABLE WATER POWER. A lakelet of pure water, about two and a half miles long and one wide, located among the Tolland hills, just outside of Rockville, and 16 miles north-east of Hartford, Conn., affords one of the most remarkable and thoroughly utilized water powers of this country. The lake, called "Snipsie," contracted from the old Indian name "Shenipsit," was originally much larger. The dam, now 30 feet in height, which, with proportionately increased expense, might be doubled, is wedged into rocks like a keystone in an arch, and perfectly controls the sheet of water that flows over it. The full fall now used aggregates 283 feet, and is utilized in falls, varying from 10 to 89 feet, by innumerable mills for silks, satinetts, cassimeres, worsteds, woolen and cotton goods, etc.

PAPER BOTTLES ARE NOW MADE ON A LARGE SCALE in Germany and Austria. The paper must be well sized. The following is said to be a good recipe for the paper: Ten parts of rags, forty of straw, fifty of brown wood pulp. The paper is impregnated or coated on both sides with sixty parts of dehydrated fresh blood, thirty-five parts of lime powder, five parts sulphate of alumina. After drying, ten or twelve rolled leaves are coated again, placed over each other, and then placed in heated moulds. The albumen in the blood forms a combination on pressure with the lime which is perfectly proof against spirits, etc. The bottles are made in two pieces, which are joined afterwards.

CHEAT METHOD OF PRESERVING FENCE POSTS.—A writer in a contemporary journal says: "I discovered, many years ago, that wood could be made to last longer than iron in the ground, but thought the process so simple that it was not well to make a stir about it. Posts of any wood can be prepared for less than two cents apiece. This is the recipe: Take boiled linseed oil, and stir in pulverized coal to the consistency of paint. Put a coat of this over the timber, and there is not a man that will live to see it rot." The experiment is a very simple one, and well worth a trial.

ADVANTAGES OF THE CABLE RAILWAY.—A leading advocate of the cable railway system declares that its main advantages over the whole method of propulsion by horse-power are as follows: First, increased speed; second, the ability to provide transportation to the full requirement of the public, even during what are called commission hours; third, cleanliness; fourth, absence of noise caused by the clatter of horses' hoofs; fifth, freedom from snow blockades in winter; sixth, superior construction of the cars and tracks.

TO OBTAIN A MAHOGANY COLOR.—A wash of one part nitric acid in ten parts of water will impart a stain resembling mahogany to pine wood that does not contain much resin. When the wood is thoroughly dry shellac varnish will impart a fine polish to the surface. A glaze of earmine or lake will produce a rosewood finish. A turpentine extract of alkanet root produces a beautiful stain which admits of French polishing. Asphaltum thinned with turpentine makes an excellent mahogany color on new wood.

AN IMPROVED FISH-HOOK has been invented by a Southern sportsman. About midway up the shaft of the hook he places a small cross bar, which serves three purposes. First, it prevents the fish from swallowing the hook; second, it increases the chances of capture, for the reason that when a fish strikes his nose against the projection it involuntarily closes its mouth and so is securely caught; and third, it prevents the bait from slipping up the hook.

COLORING SILK.—Dr. Koller says that if silk tissues are impregnated with chromate of copper and then exposed to the direct sunshine, various shades of brown may be obtained, and the fabric is rendered waterproof.

A CAMEL can carry a ton. There are 25,000 camels in Kuldsha and Erivan districts, Russia.

The Kalnucks have about 20,000 and the Khirgese not far from 10,000. Camels are bred for their labor principally, but also for their hair and milk. A camel will shear from 18 to 22 pounds of hair. This is worth in the open market about \$2.50 a pound.

ASBESTOS ROPE.—The manufacture of rope from asbestos is likely to become an industry of considerable importance in England, the strength of the article being estimated at about one-fourth that of ordinary hemp rope of the same diameter. Rope of this material of 1½ inches in diameter is stated to have a breaking strength of a ton, and 20 feet of it are calculated to represent a weight of 13½ pounds. Some of the purposes, as enumerated, to which this kind of rope is especially adapted, are theaters, fire brigades and means of escape from public buildings, its advantage being that it will not break and drop its burden if the flame bears upon it. It is made like ordinary rope, and is spun from Italian asbestos thread.

TO SOFTEN HARD RUBBER.—Rubber rings such as are used on fruit cans often become hard and brittle. They can be restored by letting them lie in water in which you have put a little ammonia. Mix in this proportion: One part ammonia and two parts water. Sometimes they do not need to lie in this more than five minutes; but frequently a half-hour is needed to restore their elasticity.

CALIFORNIA stands fifth in the list of States in the manufacture of salt, and it is the only State in the Union where the distillation of salt from sea water is carried on to any considerable extent. This industry has increased rapidly during the last twenty years. The production has risen from forty-four thousand bushels in 1860 to upwards of eight hundred and eighty thousand in 1883.

PAPER INSTEAD OF CEDAR FOR LEAD PENCILS.—They are using paper instead of wood in Germany in the manufacture of lead pencils. The paper is steeped in an adhesive liquid, and rolled around the core of lead to the required thickness. After drying, it is colored to resemble an ordinary cedar pencil. The pencils thus made sell in London at 75 cents a gross.

POWER EMPLOYED IN WALKING.—A recent calculation shows that a man weighing 160 pounds and running a mile in six minutes performs work about equal to that of a half-horse engine, while a walker sustaining five miles an hour for a long day does work equal to that of a quarter-horse engine, and consumes only one-twentieth of the weight of food or fuel.

METAL VS. THE USUAL MATERIAL FOR STRINGED INSTRUMENTS.—Recent experiments with stringed instruments have shown that a much more sonorous tone can be obtained with metal strings than with those now in use, although the labor of playing upon them is correspondingly increased. Steel wires plated with silver or copper gave the best results.

TO MAKE IRIDESCENT GLASS.—Before it is put into the annealing furnace, and while it is yet hot, a vapor is passed over it, the product of a mixture of proto-chloride of tin, carbonate of baryta and carbonate of strontian.

DRESSING FOR LEATHER.—Some one says a good dressing for leather is made of one quart of vinegar, two ounces of spermaceti oil, and six ounces each of molasses and ivory black.

GOOD HEALTH.

"Electrical Medication" Again.

EDITOR PRESS:—Under the head of "electrical medication," we are informed in your PRESS of April 19th that the medical faculty has at last, to some extent, recognized the value of "electrical medication," whatever "medication" may mean in that sense. Of course we are glad to be informed that the faculty are following along, however slowly, after the discovery of facts known and practiced outside of the profession for so many years. I should not deem the article referred to as calling for attention except for the quotation with which it closes, which gives at a glance the true inwardness of the publications made by the medical faculty, viz: "Electricity is simply force, and like other therapeutic measures must be rightly applied if we expect to accomplish much good with it. To be sure a mere novice may relieve and cure people with electricity, knowing but little about what he is doing, but this is accidental, and such ignorant practitioners are liable to do as much harm as good."

The statement is false. Who has been injured by the ignorant use of electricity as applied for remedial purposes? Such a remark would be truthful applied to many drugs used by the profession, for not one family in a hundred whose members have been treated are free from their visible effects. Finding that electricity has found its own way into public favor as a harmless remedy, to the extent of greatly interfering with their practice and profits, the faculty seem desirous to take entire charge of it and create the future impression that it is hurtful, except in the hands of the profession. Some years ago the writer was in San Francisco and had been for two weeks hardly able to get his coat on without aid, on account of rheumatism in the shoulder. Passing down Washington street, near the post office, one day, a friend invited me to test my endurance on one of the dime-show batteries which were exhibited on the street. I did so and passed on, not thinking of the rheumatism till next morning, when, to our surprise, we had no trouble in putting on our coat. The rheumatism was gone. Of the hundreds who handle electricity and magnetism in the ordinary way have never known any one to be injured, but have known of many being relieved from great suffering and restored to health. The public are not to be hoodwinked out of their common sense in regard to medicine and the common laws which govern health by publication of nostrums by the faculty, and the sooner the medical writers of books understand us, the better for them. No amount of legislation can force health-destroying drugs into use; no amount of sophistry can disguise a false statement like the one referred to. E. M.

While in part, at least, the above opinion may be correct, the fact that "E. M." has never seen cases of harm from inexperienced practice should not lead people with sensitive, weak or delicate conditions to use the battery with impunity.

Tar Smoke for Diphtheria.

Ruth Lockwood, the nine-year-old child of Thomas Lockwood, a compositor in the *Pines* office, became violently ill with diphtheria on Tuesday night. She was so weak that it was deemed dangerous to try tracheotomy, or cutting open the windpipe. On Thursday Dr. Nichols of 117 West Washington place, who was attending her, received a copy of the *Paris Figaro*, which contained a report made to the French Academy of Medicine by Dr. Delteil. Dr. Delteil said that the vapors of liquid tar and turpentine would dissolve the fibrinous exudations which choke up the throat in croup and diphtheria.

Dr. Delteil's process was described. He pours equal parts of turpentine and liquid tar into a tin pan or cup and sets fire to the mixture. A dense resinous smoke arises, which obscures the air of the room.

"The patient," Dr. Delteil says, "immediately seems to experience relief; the choking and rattle stop; the patient falls into a slumber and seems to inhale the smoke with pleasure. The fibrinous membrane soon becomes detached, and the patient coughs up micrococci. These, when caught in a glass, may be seen to dissolve in the smoke. In the course of three days afterward the patient entirely recovers."

Dr. Nichols tried this treatment with little Ruth Lockwood. She was lying gasping for breath when he visited her. First pouring about two tablespoonfuls of liquefied tar on an iron pan, he poured as much turpentine over it and set it on fire. The rich, resinous smoke which rose to the ceiling was by no means unpleasant. As it filled the room the child's breathing became natural, and as the smoke grew dense she fell asleep.—*New York Times*.

ARE BAKING POWDERS UNHEALTHY?—A writer in the *Journal of the American Medical Association* avers that there is no doubt that baking powders, even the best of them, are damaging to health. He says: To make the matter clear, it may be stated that the average baking powder is composed of bicarbonate of soda, cream-tartar, and starch, with a possible admixture of other things. The continued use of even this purest baking powder will affect the system seriously, commencing with only a slight derangement of the digestive organs, which gradually becomes chronic, changing the secretions of the stomach necessary for digestion (muriatic acid); in fact, altering the whole chemistry of the human stomach. The continued use of alkalis in any form injures the health. Look at the alkali country west of us where the alkali is found in the drinking water. The same dangers will arise from the persistent alkaline medication of our daily bread. The various forms of dyspepsia, bladder troubles, Bright's disease, and consumption—the newest researches speak about a wrong proportion of the alkalis in this disease—are only too often caused by the employment of this modern substitute in place of the old time-honored, common sense practice of using yeast.

DEATH.—Death is a part of life. It is nothing more than the negation of life. If life, therefore, be no general good, death is no general evil. Who shall decide it? Not women and children, but wise men. Thales, the chief of sages, held life and death as things indifferent. Socrates, the greatest of all philosophers, speaks of death as a deliverance, and so does Cicero and Solomon, who had tasted all the sweets of life, condemns the whole as vanity and vexation.—*Fielding*.

HEALTH.—O blessed health! thou art above all gold and treasure; 'tis thou who enlargest the soul, and openest all its powers to receive instruction, and to relish virtue. He that has thee has little more to wish for, and he that is so wretched as to want thee, wants everything with thee.—*Sterne*.

TO REMOVE INDIA INK.—Blister the part with a plaster a little larger than the mark; then keep the place open with an ointment for a week; finally dress it to get well. As the new skin grows the tattoo will disappear.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

VOLCANO.—Amador *Dispatch*, June 7: Mining interest has been rather slack for some time past. Gillick & Phillips are at work on their claim, and are taking very rich rock out. The Acme mine has started up; the mill is running day and night. Capt. Hopkins is here at present. The tunnel Co., are at work making preparations for cleaning up.

LAMBING GRAVEL CLAIM.—Amador *Ledger*, June 7: Work is still being prosecuted on this gravel claim near Irish Hill, Lone valley. About 30 Chinamen are working on shares, and making average wages, so we are informed. In addition to this, Mr. Lambing, the owner, is preparing to work the same on an extensive scale. The deposit is in a former creek bed, with 20 ft of soil to be stripped off before the pay-dirt is reached. One of the main difficulties has been to control the great flow of water. This has been mastered by putting in two powerful pumps in the pit already sunk to the bedrock to the depth of 35 ft. This, it is believed, will enable the 100 acre basin to be worked without serious obstacles as far as water is concerned. But the most formidable difficulty has been, and still is, to get rid of the enormous quantity of non-gold-bearing top dirt. At first horse-power scrapers were used, but these were speedily discarded as too slow and costly. After careful study, Mr. Lambing concluded that a derrick operated by steam power is the most feasible plan of overcoming the difficulty. The necessary machinery to this end is now being made at Knight & Co's foundry.

SUTTER CREEK.—Affairs at the Mahoney mine are beginning to assume a more lively appearance. The water is now out below the 800 level, and will remain that way until the shaft is repaired, which is expected to take about a week, when the remainder of the water—about 100 ft—will be taken out. This can be done in a couple of days, as there are no tunnels in this distance. After the water is out, the first work undertaken will be sinking 100 ft at least. This is to be let by contract to the lowest bidder. Drifting in the 800 level is likely to be commenced about the same time, with a view to connect the Mahoney with the Wildman, thereby giving good ventilation. A few additional men have been put to work, and in the course of a week or two many more will no doubt be put on. There are plenty of idle men here, however, to supply the demand. Good rock is reported to have been struck in the Lincoln by Mr. Stewart, and is being hoisted to the surface. The extent of the ore body remains to be seen.

Alpine.

STARTED UP.—*Monitor Argus*, June 6: The Illinois & California mine, in Raymond district, started up this week. Mr. Coleman has charge of all operations at the mine. Very rich ore is being taken out of the Polar mine this week. The vein is steadily increasing in size and richness. Specimens of the ore that were shown to us exceed in quality any we had ever seen before.

Calaveras.

VALLECITO.—*Cor. Mountain Echo*, June 7: Mining operations in the Balaklava district are lively in the extreme. All the claims there are being actively worked, and as near as I can learn, results are generally favorable. It is reported that Mr. T. Keyser, has sold his one-third interest in the famous Keyser mine to Luke Sanguinetti. It is also said the owners of this mine have developed an immensely rich body of gravel. That their prospects may continue favorable, is the desire of all, as the Co. is deserving of a valuable mine for the vast amount of labor they have done in opening the mine. Tyler & Co. have developed their mine sufficiently to insure them a big summer's work. It is said that a washup recently made in the Moffitt drifting mine, yielded an average of ten dollars per foot. This mine is supposed to be the richest placer mine in this vicinity. Quartz prospectors are quite reticent at present.

QUARTZ VEIN.—Mr. Messer, who is working the Old Parnell mine, near Smith's Flat, recently discovered a quartz vein about six inches in width, from which he has frequently obtained as high as \$10 to the pan. We were shown a specimen of the ore being extracted from the mine, which is immensely rich.

El Dorado.

DRILLS.—*El Dorado Republican*, June 7: H. H. McClellan, Supt. of the Melton mine at Grizzly Flat, was in town this week, making arrangements with H. S. Mory for the purchase of two National drills for use in the proposed new tunnel in his mine. An air compressor is expected in Shingle Springs from Virginia City to be used in running the drills. It is a four drill compressor, and weighs 5000 pounds; but the full capacity will not be used at first.

THAT NEW PUMP.—The exact size and capacity of the new mining pump at work at the Lamoille mine, of which mention was made as being one bound to commend itself to mining men, is as follows: Diameter of steam cylinder eight inches. Diameter of bucket six inches. Diameter of plunger four and one-fourth inches. Ten inch stroke. The capacity is 50 gallons per minute. There is a suction condenser attached, which does away with the nuisance of escaping steam up the shaft.

Fresno.

COARSE GOLD.—*Cor. Fresno Expositor*, June 7: A French Co. has taken hold of Quartz Mountain, and things in that section are getting very lively; they have commenced a survey from the San Joaquin river for a ditch to bring in water a distance of twenty-five miles. The Last Chance mine, owned by McKenzie & Rule, is opening up well; they keep their mill running steadily. The Texas Flat mine is paying well. The Hawk-eye mine, owned by Lang & Co., keeps its mill running day and night, and is turning out considerable bullion. The Morning Star mine, owned by Hardman & Mandeville, will be a bullion producer at no distant day. The Constitution mine, owned by Baker, Crane & Anderson, is looking well. They have a vein of paying ore at the bottom. The Enterprise Co. are putting up an air compressor and Burling drill. The snow is going off from Mt. Raymond, and prospectors are beginning to go into that section which, no doubt,

will be another bullion producer for Fresno county. Los Angeles.

SAN GABRIEL CANYON.—*Los Angeles Times*, June 7: Mr. A. S. Robbins returned a few days ago from a visit to the Kelsey mine, in which he, with several other gentlemen, are interested, bringing with him some selected specimens of ore, which are almost fabulously rich. Some of the specimens are as full of native silver as to be almost pure silver, and could a ton be collected, would run at least \$25,000. He does not wish it understood that the ledge, or any great portion of it, is so fabulously rich, but the numerous specimens brought in show that the mine is very rich. When placed upon a grindstone the specimens show a polished surface of pure silver. The Kelsey mine is the property of the San Gabriel Mill and Mining Company, and is located in the San Gabriel canyon, about twenty-five miles from Los Angeles. It is situated on the mountain side, at a considerable elevation above the bottom of the canyon, and the company has constructed a trail, so that they can have communication with the mine at any stage of water. The ledge has an average width of three feet, and the ordinary grade of ore runs from \$20 to \$40 per ton. A good force of men are at work running a tunnel and opening the mine, and if the prospect continues as favorable as at present appearances indicate, the company will shortly erect a mill for the reduction of the ore.

Mono.

BODIE CON.—*Bodie Free Press*, June 9: During the week 105 tons of ore were reduced at the Bodie Tunnel mill and 128 tons at the Bodie Con. mill. The average assay value of the pulp was \$16.06, and of the tailings \$2.43. They stopped crushing at the Bodie Tunnel mill on Wednesday morning, the 4th, therefore they will have but two and a half days' run at this mill and the week's run at the Bodie Con. mill to ship this week. They commenced working the one-half of the Bulwar-Standard mill late on Friday evening. The ore extracted during the last week is from the Gildea, Vulcan, Fortuna and Bruce veins. They are extracting ore from the Fortuna vein, 550 ft (Lent shaft) level. They have started a raise on the Fortuna from the 500 ft Jupiter level, and are getting some fair ore. They are breasting on the second incline level and on the 432 foot Bodie shaft level, Fortuna vein, and also on the 306 level on the Fortuna and Vulcan veins. The rich chimney of ore still continues as they raise on it north of No. 1 raise, on Fortuna vein, from 300 foot level. They are stopping on the 206 foot level on the Gildea, Vulcan and Bruce veins. The ore breasts are all looking well. They will quit to-day hauling to the Bodie Con. mill and when the ore which is at the mill is reduced they will commence to work the tailings and concentrations that have been saved from the present and former workings.

BODIE TUNNEL.—They advanced 20 ft on the vein on the 200 foot level.

HUMBOLDT HILL.—The Humboldt Hill mill of twenty stamps, situated near Aurora, started up last Monday.

MONO.—On the 260 foot level east crosscut is in 324 ft; a gain of 15 ft during the past week; passed through blue formation into red porphyry. The 400 foot level crosscut, east on the Bruce vein, is in a distance of 6 ft; a gain of 17 ft during the past week.

PLACERS.—*Homer Mining Index*, June 7: County Supervisor William Wetherill has made preparations to begin mining operations in Rancheria Gulch, which leads from the Sinnamon Cut in the Old Mono diggings eastward, emerging into Mono Lake valley through a narrow gorge about one mile west from Hector's station. This gulch has long been known to be rich in placer gold, but the drawback has been the presence of quicksand at depth, the absence of water for washing and the supposed impossibility of drainage. Mr. Wetherill, however, has succeeded in reaching bedrock, and is satisfied, that he can drain the diggings by a short cut through rimrock near the mouth of the gorge. It is now understood that the San Francisco attorney of the old J. D. Wilson Detroit Copper Company has settled up such bills of that company as had been rendered unavoidable by process of law, and that work will be resumed on the property by the old company at the expiration of the six months from the date of Sheriff's sale of the property. The Lake canyon road to the May Lundy tramway is now in good condition, and the repairs to the tramway are nearly completed. The underground force is being steadily increased, and will probably be run up between 150 and 180 men (May Lundy and Lake View) for the summer. The coming week will see both mine and mill under full headway. The Bryant is being steadily worked, and it is now reported that Supt. James McDonald, who went to Hawthorne last Saturday, to consult with Hon. Pat. Reddy, one of the largest owners of the mine, extended his trip to San Francisco to see about getting a mill. Meantime the two-stamp mill in Lake canyon will be employed on Bryant ore, of which there is a large quantity, and of high grade, in sight on the 130 level. The Gorilla is employing quite a number of men on repairs and preparatory work, besides those engaged on contract works in the mine. The company's reduction works have been running during the week on a large pile of ore. The Virginia creek hydraulic works were started up on Sunday morning last, under a head of 400 inches of water. Work is progressing favorably in the Great Sierra tunnel, Tioga district, the rock still being soft and favorable. It is now quite probable that the Sheepherder lode will be reached by or soon after the close of the present month.

Nevada.

CLEANING BEDROCK.—*Tidings*, June 7: W. J. Madden, of Smartsville, is in town, and he reports Smartsville as being very dull, owing to the mines being closed down. He says, however, at present many men are engaged in cleaning up bedrock in expectation of making it lively. Mr. Madden has been engaged in taking out the flumes of the Golden Gate mine, and has finished cleaning up enough to pay all expenses and also all the back labor accounts against the mine.

BANNER HILL.—*Tidings*, June 4: Mining in the vicinity of Banner mountain is "looming up," as it were, and several active and encouraging prospects are being carried on up there. The North Banner, mostly owned by Grass Valley parties, is improving constantly. The ledge has been quite small of late, but now it has widened out considerably and gives every indication of being permanent.

The company will soon begin the construction of a water ditch at the mine, by which free water may be obtained the entire year. When this ditch is completed, five additional stamps will be placed in the mill. The recent enlargement of the ledge enables the miners to take out quartz enough to keep the mill running day and night. Two Frue concentrators now do the work of saving the valuable part of the pulp at the Banner. Near the North Banner, and on the opposite side of the mountain, is a prospect known as the Yosemite, which is said to contain the richest rock ever found in that part of the country. The ledge is over a foot in thickness and was worked to a depth of 50 ft, gold being found in many portions of the rock, and the dirt around it being filled with coarse gold. At the depth attained water drove the miners out, and they being unable to erect machinery on the property had to abandon work until other means could be devised. The men who own the property told several Grass Valley gentlemen of the case and showed them some of the quartz. The Grass Valley men immediately took stock in the enterprise and started a tunnel on the lower side of the hill, for the ledge, and is now in about 260 ft, and will tap the ledge at about a distance of 20 ft more. The tunnel has been run with exceeding difficulty, as the rock is very hard, being serpentine in nature, and had to be blasted every inch. Peter Irving is one of the original owners of this location, and Mr. Dunnington is now associated with him in running the tunnel; two other men are also employed to assist them. It is expected that the ledge will be tapped some time in July.

DRIFT MINING.—*Transcript*, June 11: When Hirschman & Co. quit hydraulicizing this season they were in a rich part of the channel, the gravel in the face of the bank showing well in gold. Monday they began running a tunnel into the deposit, and will give a fair trial to the drifting process. The indications are that the experiment will prove successful, as the channel in this claim is not deep, and the gold is perhaps coarse enough to be principally concentrated near bed-rock. Drift mining has not paid as a rule heretofore in this section, but if the Hirschman can be made to pay by it other miners will be encouraged to give it another trial. The tunnel in the above claim runs north. Starting from the face of the same bank, and near by, J. Garthe & Co. are running in a westerly direction to tap the lead in the Knickerbocker claim. Their work has been greatly facilitated by the discovery of an old tunnel that merely needed cleaning out part of the distance, and they are now in about 75 ft. To-day they expect to be fairly into the channel. They are putting in a well built track, large and strong cars, and making extensive preparations for the thorough prospecting of their ground. If everything goes well, they will increase their force of miners in a couple of weeks.

NEW YORK HILL MINE.—*Grass Valley Union*, June 10: In addition to the good quartz recently taken out of the tenth level south of the New York Hill mine by tributaries, some good prospects are being obtained on the eleventh level north, which are expected to lead up to a body of good ore.

GOOD CLEAN-UP.—*Mansau & Co.* had a clean-up a few days ago at Perrin's mill of 42 loads of quartz from the Slate Ledge mine, which yielded \$52 per load.

MURCHIE.—*Nevada Transcript*, June 6: At the Murchie mine the full complement of 18 stamps are running regularly and with reasonably good results. Driftings being done on the 600 and 700 foot levels. Some rather high grade ore has been taken lately from Alice Bell ledge, 18 or 20 tons, having been sold on the dump to O. S. Maltman for \$45 a ton. Considerable ore that will pay about \$15 a ton is being taken from the same ledge. At the Wilson Ranch an upraise is being made from a crosscut of the mine drain tunnel, and very encouraging indications are met with. Five or six men are employed and the work is making good progress. The management expects to erect machinery on the claim this summer. Ole Helgeson has recommended tunnelling the south side of Big Canyon creek, opposite the Norway mine. Mr. Helgeson while working the same grounds a few years ago made such rich developments that we are told that he was offered \$8,000 for the property, but refused to sell, as he thought he could get more out by working it himself.

BANNER MOUNTAIN.—The ledge of the North Banner has widened out and otherwise improved lately, and the owners feel quite encouraged. A ditch is soon to be run to the mine to give free water all the year, and then five more stamps will be added. The mill now runs day and night, and the sulphurets are saved with two Frue Concentrators. The *Tidings*, from which we get the item about the North Banner also has the following relative to a rich strike on the other side of the mountain. It is called the Yosemite, and is said to contain the richest rock ever found in that part of the country. The ledge is over a foot in thickness and was worked to a depth of 50 ft, gold being found in many portions of the rock, and the dirt around it being filled with coarse gold. At the depth attained water drove the miners out, and they being unable to erect machinery on the property had to abandon work until other means could be devised. The men who owned the property told several Grass Valley gentlemen of the case and showed them some of the quartz. The Grass Valley men immediately took stock in the enterprise and started a tunnel on the lower side of the hill, for the ledge, and it is now in about 260 ft, and will tap the ledge at about a distance of 20 ft more. The tunnel has been run with exceeding difficulty, as the rock is very hard, being serpentine in nature, and had to be blasted every inch.

Plumas.

ROUND VALLEY.—*Greenview Bulletin*, June 4: The Old Round Valley ledge is now being worked by J. S. Drury. The upper tunnel has been run 350 ft. and is in a chimney of pay ore. The ledge is about seven feet wide and is between well defined walls. The next tunnel penetrates the mountain at a perpendicular distance of 250 ft below the upper tunnel. It is now in 600 ft, but not far enough to reach the first Wiles chimney by 200 ft. If the chimneys go down, and there is no room to doubt that they do, backs of from 700 to 800 ft may be secured by running another tunnel. Mr. Drury is confident that he has a valuable piece of property.

THE SUNSET.—The drift which was started two weeks ago has reached the ledge 150 ft from the prospect on top. Drifting on the ledge is now in progress. The ore removed prospects well and is being run through the mill. In an easterly direction from the Firminstone works is a ledge 7½ feet wide.

It was recently found, and prospects uniformly and gives satisfactory milling returns. From two ledges in addition to those mentioned, good ore is run through the mill. For the work done on the property, the showing which this mine has already made is very gratifying. The company have a ten stamp mill. The mill is well arranged. The location of the mine is such that great depth can be had at various points with short tunnels. G. P. Cornell and Will Blood arrived from San Francisco to-day. Mr. Cornell has possession of the Indian Valley mine now, and it is to be hoped he will begin work on the property soon. D. McDonald begins work to-day running another tunnel on the Bonanza ledge. Thus far the ore has paid well. Work on the Lucky S. ledge is progressing satisfactorily. Geo. Brandt is prospecting a ledge by crushing the ore in an arrastra. Johnson & Bicknell are running their hydraulic claim, fair prospects.

PUMPS BROKEN.—*National*, June 7: The pumps in the Riverdale mine let down again a few days since, and the drifts and shaft are again full of water. Both pumps quit at about the same time, and the water raised over them at once. The owners are arranging to put in new machinery, and this time it will be of such good capacity that there will be no trouble in handling the water. The gravel was improving rapidly when the pumps stopped, and the mine was looking better than ever. The east drift was nearly into the deep channel, which is thought to be very rich, and three days' more work would have bottomed it. It will be there, however, when the new machinery comes, and then the owners will be in better condition to handle it.

Placer

IOWA HILL.—*Placer Herald*, June 7: A. D. Bowley, of Iowa Hill, was in Auburn a short time last Wednesday, and in answer to a question as to how the times were at the Hill, he remarked: "Well, we are taking out the nuggets." He then, as proof of his statement, proceeded to exhibit several hundred dollars worth of handsome washed gold specimens, ranging in value from about \$1 to nearly \$100, recently taken out by him from the Golden Gate drift mine, located near Iowa Hill. He thinks without doubt he is on the famous Succor Flat channel, and the appearance of the gold goes to prove that he is. The old Succor Flat drift mine is working quite a force of men and is still doing very well. Other mines in the district, he reports as panning out first rate, which gives to Iowa Hill and vicinity quite an active appearance and an encouraging outlook.

San Bernardino.

MINING SALE.—*Calico Print*, June 7: R. H. Lewis has sold his claims the Mayflower near Old Woman springs to Dr. Thompson for \$6,000. Mr. Lewis will receive \$2,000 in a day or two, the balance to be paid within thirty days. Mr. Lewis will assume charge of the development shortly.

DISTRICT DIVISIONS.—A new mining district has been formed called the De Soto. It is divided from the Lava Bed district by a line which runs from the railroad to a point five miles north-west of the Morning Star mine and taking in the Hot and Old Woman Springs.

PROVIDENCE DISTRICT.—Mr. Thomas Ewing Superintendent of the Providence mine, called at the *Print* office Monday. He reported everything in first class shape, and said that the mill had been shut down for five or six days to repair worn machinery. This is the first stoppage of the mill this year. The Providence people have made a practice of keeping the ore ahead of the mill, and they have about a half a million still lying on the dumps. The Alhambra mill at Hawley has closed down for a few days in order to make the necessary changes in removing the present crusher and replacing the same with five stamps which Gov. Dagget has purchased in San Francisco.

SAMPLING WORKS.—The sampling works commenced operations last Wednesday. We learned from Mr. Olmsted that the machinery works smoothly and satisfactorily and that the works are now prepared to sample all kinds of ores. It will not be necessary now for mine owners in Calico and neighboring districts to ship their galena, copper, silver, or refractory ores to a great distance for treatment, and to find a market for them, for they now have excellent facilities at home for disposing of their ores at a good price. Since the mill began several lots of high grade ore have been sampled, giving from 800 ounces to 2,500 ounces to the ton in silver. The outlook for a busy summer for the mill this year is quite encouraging.

Shasta.

BRUNSWICK MINE.—*Trinity Journal*, June 7: In company with J. R. Balch and P. A. Lefren we paid a visit to the Brunswick Mine in French Gulch District on Saturday last. The Company were unfortunate in having their cabin, blacksmith-shop, tools, etc., destroyed by a forest fire last summer, and work has been retarded this Spring by their being compelled to make an entirely new start. However, everything is now in order for work and they were to commence taking out ore from the incline on Monday last, Chas. N. Creamer being in charge as foreman. This mine is said to be the best prospect in that section of country and lies in the best possible location for working. Fifty to sixty tons of ore are now on the dump which is variously estimated at from \$50 to \$100 per ton and it is thought two men can add to this at the rate of five tons per day. The ledge is well defined, four feet in width and has been traced about 800 feet on the surface; there is an incline of forty feet, a perpendicular shaft of 104 feet and a tunnel tapping the lode at the bottom of the shaft. Nearly all the stock of this Company is held in Trinity County and the owners propose to run the mine for all it is worth. Should the pay chute continue as it now promises, a mill will be erected within the next few months.

Sierra.

THE HOPE QUARTZ MINE BONDED.—*Sierra Tribune*, June 7: G. V. Williams & Company have bonded the Hope quartz mine at Minnesota for a term of six months. Mr. Williams has already put six men at work in clearing out the old tunnel. When the face of the tunnel is reached a shaft will be sunk and crosscuts run on the ledge both east and west. Work will also be carried on in the stopes. The Hope claim is adjacent and an extension of the Plumbago, which mine has been often referred to in these columns. The Hope property is very highly spoken of by parties who are capable of judging a good mine.

Among the owners are James McNaughton and J. T. West, of Forest City, and Al. Bixby and J. H. Clute of Alleghany.

Siskiyou.

THE McCONNELL MINE.—Yreka Union, June 7: Wm. McConnell's mining claim, on Klamath river, will yield handsomely this year, and is in better working condition than any similar claim in the county. A new pump has just been put in, which, in connection with the old one, will afford the best of drainage, and the two electric lights to be used will be in operation in a short time, but until then no night work will be done. In a run of three days, a short time since, nearly \$500 were cleaned up, and the work was not fairly under way.

BUCKEYE FUR CLAIM.—Dogget and Lasconce have just put in a new derrick in their claim two miles above Oak Bar, and are working 11 men.

JACKSON AND CRARY left good prospects in their claim on the Klamath, near Oak Bar, last fall, and have resumed work this summer, where they left off with every indication of enjoying a profitable season.

COLE AND MOTT, on the Klamath, have just put a new wing dam, and made other improvements sufficient to insure them a good run. After twenty-five years, James O'Connell, of Douglas county, Oregon, has returned to O'Connell's Bar, on the Klamath river, to develop a claim which he prospect in early days, and which has never been touched by a pick during that period. Barton and Leduck are putting in a wing dam in the Klamath river, four miles below Oak Bar, and are encouraged in their work by the knowledge that the China claim above paid exceedingly well last season. The Klamath quartz mine, located in the Salmon district, and formerly owned by Lieut. Governor Daggett, is coming to the front. Last month the company realized \$600 over and above running expenses, and the outlook for this month is far better.

Trinity.

EASTMAN DISTRICT.—Trinity Journal, June 7: John W. Blakemore tells us that the Blakemore mine continues to pay regularly and well. From Sam. Hurlburt we learned that Newman & Hurlburt had lately made a \$500 clean-up from their mine in this district and consider they have a good thing. Although 14 tons of stuff was run through the arastra it is estimated that there was not more than 5 tons of quartz in it all. We also learned that Hickey had found quartz again in his tunnel and that other workmen on Eastman and Jennings gulches had good prospects.

CROWDING WORK.—From Mr. E. M. Benjamin, Superintendent of the Hayes Red Hill Gold Mines, we learn that work on the ditch, flume, iron pipe and mine is being pushed with the utmost vigor, 50 men being at present employed in the various work. It is intended to have the Canon creek water on these promising mines at the earliest possible moment and no effort or expense is being spared to accomplish this desired end at the earliest day practicable.

DEADWOOD DISTRICT.—We passed over the Deadwood road last Saturday on the way to French Gulch and took the opportunity presented to visit the Enterprise and Barted mines, from both of which are obtained very rich specimens. The Enterprise is the property of John E. Gibson, but is at present being worked by Messrs. T. C. Cox and M. Chadbourne who have arranged for a half-interest in the proceeds. Mr. Gibson is running both his arastras on Enterprise ore and the prospect is very flattering, indicating that all parties concerned have a large fortune in sight. The Barted belongs to Frank & McDonald, who are getting out large quantities of rich ore and are also engaged in the erection of a five-stamp mill for crushing it. During the spring three runs were made with their arastra on Barted rock and the average result was \$775 per ton. When the mill is in running order and set going they will take out money very rapidly. Both the mines referred to are in rich ore deep down and with every indication of holding out indefinitely. We had no opportunity of visiting other mines on Deadwood, but learned that Frick & Davis, Shafter and others of the older mines were doing well as usual, and that the later discoveries were most encouraging. Paulsen & McGregor have just started up their arastra and are anxiously awaiting results. Davidson is getting his Cannon-Ball mill erected and will soon commence crushing on Vermont ore. Lambeth has his reduction-works started and judging from the initial smoke it is probable Deadwood will soon be enveloped in a cloud. Everyone we met in Deadwood were cheerful and hopeful, as they have reason to be, for never before has so much money been taken out of a quartz mining district for the work done, and developments in every direction show that the future will confirm the most rosy views of those who are fortunately possessors of interests in that district.

NEVADA.

Washoe District.

HALE AND NORCROSS.—Enterprise, June 7: Are now daily shipping ore from the 200 level to the Mexican mill, on the Carson river, where a crushing of 1,000 tons will presently be made. On the 2300 level are easing timbers at and about the station. No work is being done on this level at the points where ore was found, but a beginning will probably soon be made, as the Savage bulkhead is now completed.

YELLOW JACKET.—The boilers from the works at the new shaft have been brought to the works at Gold Hill and are being set up in place of the old ones. Considerable exploring work is being done at several points, and some paying ore is being encountered.

BEST AND BELCHER.—Good progress is making in the northwest drift recently started on the 2500 level. The east crosscut on the 200 level is still encountering a considerable amount of quartz. It is being advanced into a very favorable formation.

UNION CON.—Are drifting in east crosscut No. 4. There is some water in the drift, but not sufficient to prevent going forward with it. The ground is a mixture of clay, quartz and porphyry, of a promising appearance.

MEXICAN.—The winze started on the 3100 level is now down to the 3000 level. It is in material so soft that it will be necessary to go some deeper in order to find firmer ground in which to open a station.

UTAH.—The southeast drift on the 1950 level has been advanced 33 ft, and continues in vein material,

with a considerable amount of quartz. As yet this quartz carries no metal of value.

ALTA.—Good headway is making in the west drift on the 2150 level, though the rock is hard. The diamond drill has been started east from the face of the east drift on the 2150 level.

IMPERIAL.—The lateral drift, now in Alpha ground, is encountering a considerable amount of quartz, but thus far it is not found to carry metal in paying quantities.

SIERRA NEVADA.—The north drift on the 3100 level has made good progress during the week. The face is in vein material of a favorable character, and the ground is dry.

COMBINATION SHAFT.—Are making good headway in cutting out the bob-station at the 2700 level and in opening out the pumping and working station at the 2900 level.

GOULD AND CURRY.—Two east crosscuts are being run on the 1200 level, in ground that shows a good deal of quartz of a promising appearance.

ANIES.—Some low grade ore is being extracted, and a good deal of work is being done in the way of exploring and prospecting.

CALIFORNIA.—The east drift on the 2000 level has been advanced about 30 ft. Have completed repairing the C. and C. joint shaft.

CON. VIRGINIA.—The east drift on the 2000 level has been advanced about 30 ft. Have completed repairing the C. and C. joint shaft.

CROWN POINT.—About the usual amount of low-grade ore is being extracted and sent to the mills on the Carson river.

CHOLLAR.—Are preparing to place a stone bulkhead in the drift on the 26 level, that in the Savage having been completed.

BELCHER.—About the usual amount of low-grade ore is being extracted on the old upper levels.

SCORPIO.—The west drift in the 500 level is still in vein material of a favorable character.

SAVAGE.—The bulkhead in the north drift on the 2600 level has been finished.

OPHIR.—Are sorting out fillings in the various drifts on the 250 level.

Belmont District.

LEACHING.—Belmont Courier, June 7: Work on the addition to the Belmont Mining Company's leaching works is progressing rapidly. They are building a foundation of stone. The mine is looking very well and considerable good ore hoisted to the surface daily. Peter Bartell and William Hall are sinking an incline on their mine north of town. The incline has already attained a depth of about 20 ft and some good ore is exposed at this depth. They will continue the work of sinking until they strike the main ledge.

Bristol District.

BULLION.—Pioche Record, May 31: The Day Company get their bullion hauled to the terminus of the Utah Central for \$12 per ton. There are some pretty copper specimens from the lead well of the furnace on exhibition at McCarter's. Foreman Walsh is about to erect a bath-house, adjoining the furnace, for the benefit of the employees. There seems to be considerable dissatisfaction among the employees at the furnace, and a strike for the old wages is anticipated. Johnny Blair put six men to work during the week—three on the Tempest and three on the Iron mine—and it is more than probable that a large force will be put on the former claim inside of a few months.

Eureka District.

THE CONNOLLY.—Eureka Sentinel, June 2: The hoisting machinery at the Connolly mine has been thoroughly overhauled, and steam was got up on Wednesday last. The mine is looking better in every respect than it has for years past. Yesterday the contractors struck into a thick stratum of soapy clay, which has the appearance of the hanging of an ore body, but no assay of it has yet been made. The tributaries, who are working in the bottom of the mine, will make a shipment of ore during this week.

Schroeder District.

A NEW CAMP.—Cor. Exchange, June 5: C. E. Ferguson, well known as a prospector and miner of many years' experience, while prospecting in the vicinity of Schroeder district in July of last year, discovered some very favorable indications of mineral. Making a thorough examination of the ground, and having various samples assayed, he became convinced that the ground was valuable. A number of locations were immediately made, and sufficient development work done to test, in a measure, the character and extent of the discovery. The work already done, though of limited extent, would seem to prove that this will be one of the most productive camps in Eastern Nevada. The prospects run from \$40 to \$300 in silver and 40 per cent lead per ton, with a trace of copper and antimony. Most of these claims have been prospected from 10 to 40 ft in depth, and all show good indications. Everything is promising, and the owners enumerated above are very hopeful. This camp is about 10 miles from Carlin, in a south-westerly direction. It is located near Ferguson mountain, on the old Tuscarora road, along what is known as Maggie Creek—a stream of water sufficient to supply all the needs of the camp in winter and summer. The mines are owned principally by poor men, who are most of them experienced miners. Goodhue & Co. have erected a furnace at Palisade for smelting ores from their mines. A road is also being constructed from Maggie creek to the top of Ferguson mountain for the purpose of transporting ore from the mines to Palisade.

Tybo District.

GOOD ORE.—Belmont Courier, June 7: Work is progressing finely in the 2 C. mine at Tybo and good ore is being extracted from this famous mine.

ARIZONA.

BONANZA MINES.—Quijotoa Prospector, June 4: The situation this week is highly flattering. In tunnel No. 4 considerable quartz has been encountered, which gives good assays. In south drift of tunnel No. 2 some very fine ore has been cut, which thoroughly demonstrates the existence of a vein of ore at a depth of 400 and odd ft. The wise-ones, who predicted that it would never go down, have, Arab like, "folded their tents and stolen away"—it is to be hoped, never to return. There are, on good careful judgments, several millions of dollars worth of ore

exposed on the surface of the bonanza properties, and with a depth of over 400 feet to add to the surface, showing the aggregate is too astounding even to place in figures. The question of the town of Quijotoa becoming a populous one is definitely settled. It is merely a question of time. It is safe to say that Quijotoa, before next Christmas, will have a population of 2,500. For the benefit of our contemporaries we will state that the question of the erection of a mill on once has not been settled, but is now under consideration by the Board of Directors.

PEERLESS.—On Wednesday last tunnel No. 1 was in 188 ft. The rock was very hard, with seams of quartz running through it. The outlook is very favorable. South drift from tunnel No. 2 is in 56 ft. Some very fine ore has been cut in this drift.

OLD DOMINION ITEMS.—Globe-Chronicle, June 7: The output of copper hulsion for the month ending last Sunday morning at 7 A. M. was more than anticipated, being very nearly 491 tons. This is by far the largest product from two 30-ton furnaces on record, and everyone connecting with the management has reason to feel proud of the month's work. To all who aided in this grand result, from the miner to the Supt., a great deal of praise is due and could be bestowed, but to none more, we think, than to Mr. John Canavan, the chief smelter, and his assistant, Mr. Barneyburg. Mr. Canavan's large run of 402 tons a year ago, and his present run of over 490 tons, is proof positive that what he does not know about smelting copper ores and running a 30-ton furnace isn't worth knowing.

COLORADO.

MINING NOTES.—Colorado Miner, June 5: In No. 5 on the Pay-Rock mine, Proutt & Co., in sinking a winze, have opened up a good streak of ore. A fourteen-ton carload of smelting ore from the Albro mine, at Dumont, was shipped to Denver this week. A good strike of copper-bearing ore is reported at the Big Chief mine. It is said that over two ft of the mineral carrying gray copper is uncovered. The Ilukill mine was sold by Deputy Marshal Cantrill last Monday for the sum of \$14,500. At the Little Giant lode on Red Elephant, owned by C. B. Koontz, is reported a very promising strike; it is claimed that a vein of solid ore, from two to three inches in thickness has been encountered, the character of which is silver glance, ruby silver and gray copper. Fifteen stamps are at work at the Mansfield mill on the free milling ore from the Albro mine, at Dumont. Five stamps at the same mill are at work on free milling ore from the Old Settler, which is running very high in gold. The Georgetown tunnel, owned and worked by Beebe & Co., at 200 ft. intersected an unknown cross lode this week. They have penetrated this crevice about four feet, and yet no foot wall has been encountered. The whole crevice, so far, is disseminated with small particles of mineral, galena and iron pyrites. A vein of quartz from five to six inches thick, shows bunches of mineral, of what might be determined solid, but yet not quite. The Choctaw lode, located on Saxon mountain, near Alvarado, is owned by John Tomay, Thomas Barnes and Dr. Cherry, of Baltimore, Md. The work now going on is drifting and stopping from crosscut. This crosscut is 72 ft in length, and intersects with the lode 70 ft perpendicular from the surface, the drift upon the vein has reached a distance of 250 ft. The work under way is in this part of the mine, and the showing, at this writing, is a vein three and one-half inches in thickness, of solid argentiferous galena, which mills 100 ounces silver to the ton. The Sonora lode, located on Griffith mountain, within sight of Georgetown, is owned by Joseph Guannella & Co. The adit on the vein is 350 ft long, at the breast of which is a perpendicular depth of 250 ft. The breast now shows a vein of solid ore about three inches in thickness, of a galena nature, carrying gray copper. The last millrun shows 110 ounces silver, half an ounce gold, and four per cent copper to the ton. A specimen assay showed 1.035 ounces silver.

IDAHO.

PLACER CENTRE.—Cœur d'Alene Pioneer: The new camp of Placer Centre is between the mouths of Canyon and Nine-Mile creeks at the scene of the late stampede to the South Fork of the Cœur d'Alene river. A great many stories pro and con have gone abroad regarding the results of the stampede, and while the placers have not satisfied the stampedeers, still the lode has resulted in the discovery of several valuable leads that are likely to bring that region into the foremost ranks of base-metal camps. Messrs. Dowd, Wallace and Norton of Fort Cœur d'Alene, own the townsite of Placer Centre, and the Mullen road runs through it. There are now about two dozen houses in the camp. Messrs. Norton and Wallace have made an effort to reach bedrock, but without success. They ran a drain ditch 20 ft and sank 15 ft more, but were finally compelled to quit work by the flood of water which ran in. They obtained colors, however, and will resume work as soon as the water subsides. After the excitement over the placers had subsided, several of the more persevering continued to prospect up the creeks. Good colors were obtained at the mouth of Grouse creek, a tributary of Nine-mile. It is said that the prospects here are not inferior to those on Pritchard, albeit the owners are preparing to open the ground by a system of drain-ditches which have been begun. Several fine leads of galena and carbonate ores were discovered later both on Nine-mile and Canyon creeks and a little development work gives every evidence that they are of great value. The ore is high grade and carries gold in considerable quantities. The formation is granite, limestone and slate with a preponderance of the latter. The granite cleaves the slate in twain, while the limestone formation is in contact below. One of the most important finds is the Tiger, on the east side of Canyon creek, eight miles from Placer Centre. The ledge is four ft in width, and recent assays show the ore to contain 112 ounces in silver, \$20 in gold, with 35 per cent lead. Six men are opening up the claim, and have a ledge with well-defined walls. The extension on the Tiger is owned by Messrs. Wheeler and McVicker, of the Pritchard stampedeers, and they have a vein as promising as the Tiger. Across the creek from the Tiger is the Norton claim. It is a ledge of galena and carbonate ore, from two to four ft in width. The owners are sinking a shaft which is in mineral all the way from 20 ft. The Wonder, located by P. M. Barker, K. Seelye, W. B. Hays and W. W. Doty, is on the divide between Nine-Mile

and Canyon creeks, and two and a half miles from Placer Centre. The ledge is narrow, but correspondingly rich. Specimens brought to Murray are pronounced to be the finest specimens of galena ever seen. A shaft is down about 10 ft in this claim and a tunnel is started for the vein.

THE OLD WASH.—Explorations during the past week show that the old river wash is far more extensive than at first supposed. Reports from Placer Centre show that it exists on the divide between Nine-Mile and Canyon creeks, tributaries of the south fork of the Cœur d'Alene river. It is found on the hills at Evolution and near the mouth of Beaver creek, and has a course from east to west. The wash runs parallel with the old river channel on Pritchard creek, but its character is different. It is a decomposed granite, covered with oxide of iron, interspersed with well-worn boulders. Its existence can be accounted for if we suppose the main channel to be the wash on the north hill-sides along Pritchard creek, and this deposit to be on the rim. It would be a big river, it is true, but the wash would need a chaplain river to deposit it.

BUTTE.—The town of Butte is one of the suburbs of Murray, being distant only 14 miles. It is located on Pritchard creek, between the mouths of two very rich side gulches—Butte and Reeder. Butte was started last spring. Some of the best ground in the country is in its immediate vicinity, and at least 1,000 men are prospecting and mining within a short distance of the town. On Reeder gulch there are mountains of gold quartz that will in the near future make Butte a great mill point, while the placers show prospects which are not a whit behind those elsewhere along the creek. Butte creek is the main fork of Pritchard, and is 10 miles long. It carries a large head of water during the entire season. On it good ledges of free-milling and base ores have been found, although the country is comparatively unprospected. Ophir and Tiger gulches come into Pritchard creek from the south at Butte, and on both of them paying prospects have been found. Butte is where the Belknap trail first strikes Pritchard creek, and the trail from the rising camp of Carbon, at the head of Beaver creek, will come down Ophir gulch. Prospecting is lively. Everybody is looking for quartz. Quite a number of strangers are in town, looking for locations to start business. In Bonanza gulch, a tributary of Butte, there is a breeze over several large nuggets that were picked up in the gravel close to bed-rock. The prospects on the main creek are looking better every day. The old wash-gravel is found very rich at Butte, as high as 4 oz. being taken from a single pan. A tunnel is in on it nearly 60 ft, and has pay all the way. Old miners pronounce it the biggest thing yet found. Work on the Sargent claim will be begun this week. The claim is ready for the sluices, and with a decline in the water, active work will be begun and continued all summer.

MONTANA.

PHILLIPSBURG MINES.—Cor. Butte Miner, June 7: Mining matters remain about as usual; in fact, nothing very interesting can be written about such of our mines as may be undergoing development for the reason that, save and except the properties of the Hope company, nothing in the shape of ore can be treated in the camp. The Hope mill, which, now completely equipped, is running steadily, has sufficient company ore on hand to run six months, and will, of course, do no custom work. And as the statu quo of the Algonquin remains serene and undisturbed, it is highly probable that the mineral dumps or the district will have to be moved to Anaconda for treatment. With this flattering outlook for the present, we contentedly await the future.

SAN FRANCISCO.—A visit to this mine shows it to be steadily improving as the tunnel header gains depth. Three feet of ore stands in the level, much of it high grade and all of it fair. The strong similarity between the rock of this mine and that of the famous Granite mountain leads many to believe that it will eventually develop as well. It is beyond any doubt the next best property in the granite country of the camp. James Patten left for Salt Lake city during the week past.

WENGER NO. 2.—McDonald have about 75 tons of excellent rock on the dump. Work has been temporarily stayed in the mine, the owners seeing no opportunity to sell the ore now out. Four ft of 50 ounce rock lays in the face of the west crosscut from the 40 ft station. Five ton of 100 ounce ore can be easily extracted from this mine daily by stopping. Should occasion offer, the owners intend to ship to Anaconda the best of the rock they have assorted as the mine.

UTAH.

STRIKE IN THE NABOB.—Southern Utah Miner: The Beaver Lake boys feel quite jubilant over a strike lately made in the Nabob mine. Several days ago a streak of green rock was encountered in the ledge matter in the north drift, what was looked upon as poor or worthless ore, and part of it was thrown into a pile of second class ore, and part was thrown over the dump. Last week a sample of this ore was assayed with a result showing 864 ounces of silver per ton. It was almost an accident that the ore was ever sent to the assayer, and the result was a happy surprise to the owners. The ore is chloride of silver with quartz gangue. It runs for a distance of 25 ft through the ledge matter to the face of the drift, and varies in width from 4 to 6 inches. The ore body has now opened up to a width of 2½ ft, running diagonally across the drift. The ore is galena, carrying black metal and chloride of silver, and the green stained rock mentioned. The face of the drift has become soft, with seams of iron and spar running through it in all directions. The ore body has been widening out for the distance of 30 ft, and the indications are that before another 30 ft is run, the drift will be entirely in ore. There are about twelve tons of first-class, and between eight and ten tons of second-class ore on the dump. The owners will make a shipment to Salt Lake this week. Two men can easily take out between 1,200 pounds and a ton of ore daily, which will assay from 100 to 2,000 ounces of silver to the ton. This property has been abandoned for several years, the only work that was done was by chloriders, who gouged the ore out wherever they could find it, leaving hardly a trace in sight, last winter when R. S. Lipscomb took hold of the mine.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF

MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Bruntou's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Olant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jics, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Oen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

DEWEY & CO'S

Scientific Press Patent Agency.

(ESTABLISHED 1860.)

Inventors on the Pacific Coast will find it greatly to their advantage to consult this old experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

WM. BARTLING. HENRY KIMBALL. BARTLING & KIMBALL, BOOKBINDERS. Paper Rulers & Blank Book Manufacturers. 505 Clay Street, Southwest cor. Sansome, SAN FRANCISCO.

Engraving Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the MINING AND SCIENTIFIC PRESS, San Francisco, at favorable rates.

PUBLISHED OR I-SOLD, WHOLESALE AND RETAIL, BY DEWEY & CO., MINING AND SCIENTIFIC PRESS OFFICE, S. F.

BY GUIDO KUSTEL,

MINING ENGINEER AND METALLURGIST.

CONCENTRATION OF ORES (of all kinds), including the Chlorination Process for Gold-bearing Sulphurets, Arsenurets, and Gold and Silver Ores generally, with 120 Lithographic Diagrams. 1867.

This work is unequalled by any other published embracing the subjects treated. Its author is highly esteemed and regarded by its readers, containing as it does, much essential information to the Miner, Metallurgist, and other professional workers in ores and minerals, which cannot be found elsewhere in print. It also abounds throughout with facts and instructions rendered valuable by being clearly rendered together and in simple order. It contains 120 diagrams, illustrating machinery, etc., which alone are of the greatest value. PRICE, \$7.50.

ROASTING OF GOLD AND SILVER ORES (Second Edition) and the Extraction of their Respective Metals without Quicksilver. 1880.

This rare book on the treatment of gold and silver ore, without quicksilver, is liberally illustrated and crammed full of facts. It gives short and concise descriptions of various processes and apparatus employed in this country and in Europe, and the why and wherefore. It contains 150 pages, embracing illustrations of furnaces, supplements and working apparatus. It is a work of great merit, by an author whose reputation is unsurpassed in his specialty. PRICE, \$5, coin, postage free.

DOWNIE

EUCALYPTUS

BOILER SCALE

Preventive and Remover.

(Patented May 8, 1883.)

In use in 1,000 Boilers on Steamboats, Locomotives, Mills, Mines, Foundries, etc., in California. An

Infallible Preventive and Remover of Scale

Prevents the iron from rusting or pitting.

Shipped in ten gallon cases at 50 cents per gallon, by

THE CALIFORNIA POWDER WORKS.

MANUFACTURERS OF

Sporting, Cannon, Mining, Blasting and

HERCULES POWDER

HERCULES POWDER will break more rock, is stronger, safer and better than any other Explosive in use, and is the only Nitro-Glycerine Powder chemically compounded to neutralize the poisonous fumes, notwithstanding bombastic and pretentious claims by others.

It derives its name from HERCULES, the most famous hero of Greek Mythology, who was gifted with superhuman strength. On one occasion he slew several giants who opposed him, and with one blow of his club broke a high mountain from summit to base.

No. 1 (XX) is the Strongest Explosive Known.

No. 2 is superior to any powder of that grade.

PATENTED IN THE UNITED STATES PATENT OFFICE.

ORDERS RECEIVED FOR HERCULES CAPS AND FUSE.

JOHN F. LOHSE, SEC'Y.

Office, No. 230 California Street

San Francisco, Cal.

THE CONSUMERS' COMPANY.

HYDRAULIC

MINERS:

THE ABOVE CUT REPRESENTS OUR NEW IMPROVED GIANT, which we recommend as being the Best Hydraulic Machine ever manufactured. They are SIMPLER, LIGHTER, CHEAPER AND MORE EASILY WORKED than any style heretofore made. The machine is fully protected by patents owned by us, and we will guarantee protection to our customers. Send for Circular and Price List.

HOSKIN & CO., Marysville, Cal.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gauge Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrounding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

A Body Supporter.

Not long since J. W. Anderson of Bodie, obtained a patent through the MINING AND SCIENTIFIC PRESS Patent Agency, for a body and shoulder brace and straightener, the principle of which is, in providing suitable means for pressing forward the small of the back, whereby the body is kept straight, and the shoulders prevented for being thrown forward. The object is to straighten, and support the body, and by this means to cause the shoulders to be kept back, because, having the lower part straight it is inconvenient to throw the shoulders forward. From personal observation of the use of this appliance, we know it successfully accomplishes the object of straightening the wearer, and apparently with safety and convenience.

Two metal strips have pivoted to their lower ends a curved metal strip. At the top of the upper strip is a strap. The metal strips are curved to fit the body. To one of the strips at about the center is secured a strap the other end of which is adapted to be secured to the other strip, preferably by buttons and button holes. These button holes are placed at different distances upon the strap to adjust its circumference. On the center of the strap is a pad suitably covered, and the metal parts are also covered properly.

The curved strips are fitted upon the abdomen, the base strip at the bottom and the top strip above. The curves of the strip conform nicely to the part fitted. As before said, the base strips are pivoted to the base strap. This is for the purpose of allowing the adjustment of the strips with regard to their side inclination. By having a longer or shorter strap, or a strap rendered extensible in any manner, the metal strips may be drawn closer together or allowed to spread at their tops to suit the comfort of the wearer.

The strap passes around the waist, and is drawn sufficiently tight and secured on the other end, thus forming a supporting belt for the device. The stiff pad on the belt fits upon and presses into the small of the back. It keeps the back straight. There is no inclination to bend at this point, because the small of the back is sufficiently sensitive to cause the wearer to avoid unnecessary bending. The front portion upon the abdomen assists the pad. When the small of the back is thus kept straight there is no chance to give at this portion, and, as in throwing the shoulders forward, this portion bends also; when this is prevented the inclination is to keep the shoulders straight. If the lower part of the body be kept straight it is inconvenient to do otherwise than to keep the whole body in like position, and therefore the shoulders are thrown back. The device is a good support for the body, and after being worn a short time becomes comfortable. It does not interfere with other portions of the body.

We can confidently recommend those needing a supporting apparatus to try this new device, or consult Dr. Anderson as above for further information.

Mining Share Market.

The mining stock market maintains its wonted quietude, transactions being very insignificant and variations in price small. No news of any special importance comes from Bodie. On the Comstock, at the north end, the Mexican mine has just reached the 3,200 level—the greatest depth ever attained in North or South America. The material at that point is a soft mixture of clay and quartz. So soft is the ground that a station will not be opened in it.

At the middle mines all is going on about as usual. The Hale and Norcross folks are shipping from the bonanza on the 200 level eight car-loads of ore a day to the Mexican mill, Carson river. There is no mining doing on the 2800 level. The Savage bulkhead is finished, but there is now talk that prospecting will not be resumed below until the Cornish pump is in operation at the 2900 station of the Combination shaft; meantime the stock of the middle mines will be beaten down to the lowest possible notch.

At Gold Hill the leading mines are taking out and shipping the usual amount of low-grade ore from the upper levels.

Bullion Shipments.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

CRISTY M. Co., June 9th. Capital stock, \$1,000,000. Directors, Robert N. Graves, O. F. Giffin, F. A. Benjamin and W. M. Lubbock.

SONORA ANTHRACITE, COAL AND DEVELOPMENT Co., June 9th. Capital stock, \$10,000,000. Trustees, Daniel E. Hayes, P. T. Dickinson, Nathan W. Spaulding, P. McAnan and Alexander G. Hawes.

CALIFORNIA OIL Co., June 10th. Capital stock, \$1,000,000. Directors, C. C. Lane, F. Hoelling, Isaac Birbaum, A. W. Fox and N. D. Anderson.

GAVER IMPROVEMENT Co., June 10th. Object, a general mining and milling business. Capital stock, \$25,000. Directors, John Wright Jonas Call, John R. Supham, Gibson P. Kelly and C. M. Tyler.

MAGINNIS M. Co., June 5th. Principal place of business, Helena, M. T. Capital stock, \$500,000. Directors, Samuel T. Hanter, Anton M. Holter, Geo. H. Hill, Ashburn K. Barbour and Alfred M. Esler.

COMMERCIAL M. & M. Co., June 2d. Location, Centennial district, Elko Co., Nevada. Capital stock, \$250,000. Directors, Geo. W. Pelier, A. V. Lancaster, E. L. McMahan, J. W. Powell and A. V. Price.

The Russian government has borrowed \$200,000,000.

Photo-Engraving, Etc.

Some of the finest and most accurate engravings in the United States are now executed by photo-relief processes at greatly reduced rates from the prices of good wood engraving.

We are prepared to receive orders for all kinds of engravings, to be executed by photo-relief electrotype process, or wood engraving, as the style, quality and price to be paid may indicate.

We will guarantee satisfaction as to quality of work and prices.

Drawings will be made from photographs, models, paintings, sketches, etc.

Illustrations designed for books, pamphlets, circulars, letter-heads, envelopes, labels and commercial printing of all kinds on favorable terms.

Send particulars and samples of engravings wanted and ask for prices.

When requested, our city agent will call to receive orders and explanation.

Engraving by the aid of photography is comparatively new; the work is progressive; better facilities are being constantly acquired, the results improved, and the prices lowered for good and satisfactory work.

ADDRESS THIS OFFICE.

A RARE CHANCE.

A party with \$20,000 to purchase a third interest in a mine that has in it many a vein. On one there is a shaft 38 feet deep, in 4 feet of Silver King ore, assaying \$400 per ton. At the center there is a dike or lift in the belt of veins full 50 feet in width, that runs across the mine. Twelve feet from the center of this lift there is a shaft 23 feet deep, the bottom all in tale and white porphyry, streaked with veins of quartz specked with ore. This mine is 1½ miles northwesterly from the Silver King mine, in an overlooked section of country, but is in the same formation that the Silver King is in. Half of the purchase money will be used in opening and developing the mine. The party accepting this offer will draw a prize equalled by none—yes, not even by the famous Silver King—for through it surely flows the Equator of the Silver Zone. For further information, address

SAM. THORPE,
Silver King, Arizona.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO., in the shortest time possible (by telegraph or otherwise), at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and in the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s SCIENTIFIC PRESS U. S. and Foreign Patent Agency, the following are worthy of special mention:

LAYING AND SECURING RAILS.—Jeanty Denechaud, Sr., S. F. No. 299,208. Dated May 27, 1884. This improvement in laying and securing rails in the road beds of railways consists in imbedding in the cross-ties the base and lateral flanges of a peculiar rail and in securing it by a novel brace or clamp, the base of which is also let into the cross-tie. The object is to prevent spreading of rails by securing them to the cross-ties so firmly as to give solidity. The invention is applicable to any railway, but is more specially for use with a safety railway car patented by the same inventor, and in which rollers secured by arms to the car are adapted to be projected into the groove of the rails to prevent derailment.

LAP BOARD.—Adam L. Anthony, Placerville. El Dorado Co., Cal. No. 296,219. Dated April 22, 1884. The improvement consists in sliding slides or leaves and in hinged corners, whereby the lap board may be closed up to smaller dimensions, either for convenience in use or transportation. The object is to provide an extensible lap board which may be adjusted to different sizes and closed up for transportation.

Secure the Reduced Rate.

After the first of April, 1884, we announced a reduction of the price of the MINING AND SCIENTIFIC PRESS from \$4 to \$3 a year to all who would settle up arrearages at old rates and pay in advance thereafter. There are some who have not yet taken advantage of this offer, and we would therefore urge all subscribers still in arrears to remit what is due us to this date, at the rate of \$4 a year, and pay in advance for another term at the reduced rates for new subscriptions paid in advance.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

Agents.

OUR FRIENDS can do much in aid of our paper and the cause of practical knowledge and science, by assisting Agents in their labors of canvassing, by lending their influence and encouraging favors. We intend to send none but worthy men.

IRON CLAD MANUFACTURING CO.

22 Cliff Street, New York.

A Plain Book on Assaying.

"ASSAYING GOLD AND SILVER ORES"—By C. H. Aaron—Is a new work published by Dewey & Co., which is intended by its author to be available for the use of miners, prospectors and others who only care to know how to assay gold and silver ores.

The author of this work is well known in the mining regions of the Pacific coast as a practical metallurgist of many years experience. His writings for the press and his two previous works ("Testing and Working Silver Ores," and "Leaching Gold and Silver Ores") have shown his ability as a writer. The little book is plainly and simply written, more especially for the use of those persons not familiar with chemistry. No symbols are used, everything being plainly stated and clearly described. The scope of the book is shown in its table of contents as follows: Introduction; Implements; Assay Balance; Materials; The Assay Office; Preparation of the Ore; Weighing the Charge; Mixing and Charging; Assay Litharge; Systems of the Crucible Assay; Preliminary Assay; Dressing the Crucible Assays; Examples of Dressing; The Melting in Crucibles; Scorchification; Cupellation; Weighing the Bead; Parting; Calculating the Assay; Assay of Ore Containing Coarse Metal; Assay of Roasted Ore for Solubility; To Assay a Cupel; Assay by Amalgamation; To Find the Value of a Specimen; Tests for Ores; A Few Special Minerals; Solubility of Metals; Substitutes and Expedients; Assay Tables. These assaying tables give simple directions for figuring out results. This is the simplest, cheapest and most easily comprehended work on assaying yet published. The volume comprises 106 pages, with illustrations, and is well bound in cloth. The price is \$1, postpaid. Published by Dewey & Co., MINING AND SCIENTIFIC PRESS office, San Francisco—1884.

Mining and Scientific Press.

THE MINING AND SCIENTIFIC PRESS is the leading mining journal in America, and enjoys a larger circulation among the more intelligent operators and workers in the gold fields of the world.

Established in 1860, it has firmly maintained its position as a reliable, progressive journal. The information given in its columns has saved millions of dollars to the practical miners, metallurgists, mill men, mine and share holders on the Western side of our continent.

Among its contributors are the ablest and most experienced mining engineers, superintendents and practical miners in this country.

The Press gives a condensed summary of Mining News from the most important mining districts of the country. New processes and methods of mining are described in its weekly issues. New mining machinery and improvements are frequently illustrated and explained in a manner to be of great value to all interested in mining.

As a scientific and mechanical representative of the Pacific Coast it is decidedly popular, and a standard journal with the most thrifty industrial people of the Pacific States and Territories. Its authority is of the highest order, and its usefulness in its special sphere unrivalled.

Every public library, mining engineer, metallurgist, mining operator, and intelligent mechanic and manufacturer, will find profit by its reading.

Subscription, \$3 a year in advance. Sample copies, prepaid, 10 cents.

OFFICE—Room No. 69, Nevada Block, No. 309 Montgomery street, San Francisco, Cal.

Cheap Ore Pulverizer.

There is for sale in this city, by L. A. Heald, American Machine and Model Works, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below cost, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

CLARENDON HOUSE,

574 Folsom Street, N. E. Cor. Second, S. F.

Dewey & Co., American and Foreign Patent Agents.

PATENTS obtained promptly; Caveats expedited; Patent Reissues taken out; Assignments made and recorded in legal form; Copies of Patents and Assignments procured; Examinations of Patents made here and at Washington; Examinations made of Assignments recorded in Washington; Examinations ordered and reported by Telegraph; Rejected cases taken up and Patents obtained; Infringements Prosecuted; Opinions rendered regarding the validity of Patents and Assignments; Every legitimate branch of Patent Soliciting promptly and thoroughly conducted.

Our intimate knowledge of the various inventions of this coast, and long practice in patent business, enable us to abundantly satisfy our patrons; and our success and business are constantly increasing.

The shrewdest and most experienced Inventors are found among our most steadfast friends and patrons, who fully appreciate our advantages in bringing valuable inventions to the notice of the public through the columns of our widely circulated, first-class journals—thereby facilitating their introduction, sale and popularity.

Foreign Patents.

In addition to American Patents, we secure, with the assistance of co-operative agents, claims in all foreign countries which grant Patents, including Great Britain, France, Belgium, Prussia, Austria, Baden, Pomerania, Russia, Spain, British India, Saxony, British Columbia, Canada, Norway, Sweden, Mexico, Victoria, Brazil, Bavaria, Holland, Denmark, Italy, Portugal, Cuba, Ruman States, Wurtemberg, New Zealand, New South Wales, Queensland, Tasmania, Brazil, New Granada, Chile, Argentine Republic, AND EVERY COUNTRY IN THE WORLD where Patents are obtainable.

No models are required in European countries, but the drawings and specifications should be prepared with thoroughness, by able persons who are familiar with the requirements and changes of foreign patent laws—agents who are reliable and thoroughly established.

Our schedule price for obtaining foreign patents, in all cases, will always be as low, and in some instances lower, than those of any other responsible agency.

We can and do get foreign patents for inventors in the Pacific States from two to six months (according to the location of the country) SOONER than other agents.

The principal portion of the patent business of this coast has been done, and is still being done, through our agency. We are familiar with, and have full records, of all former cases, and can more correctly judge of the value and patentability of most inventions discovered here than any other agents.

Situated so remote from the seat of Government, delays are even more dangerous to the inventors of the Pacific Coast than to applicants in the Eastern States. Valuable patents may be lost by extra time consumed in transmitting specifications from Eastern agencies back to this coast for the signature of the inventor.

Confidential.

We take great pains to preserve secrecy in all confidential matters, and applicants for patents can rest assured that their communications and business transactions will be held strictly confidential by us. Circulars of information to inventors, free.

Home Counsel.

Our long experience in obtaining patents for Inventors on this Coast has familiarized us with the character of most of the inventions already patented; hence we are frequently able to save our patrons the cost of a fruitless application by pointing to them the same thing already covered by a patent. We are always free to advise applicants of any knowledge we have of previous applicants which will interfere with their obtaining a patent.

We invite the acquaintance of all parties connected with inventions and patent right business, believing that the mutual conference of legitimate business and professional men is mutual gain. Parties in doubt in regard to their rights as assignees of patents or purchasers of patented articles, can often receive advice of importance to them from a short call at our office.

Remittances of money, made by individual inventors to the Government, sometimes mis-carry, and it has repeatedly happened that applicants have not only lost their money, but their inventions also, from this cause and consequent delay. We hold ourselves responsible for all fees entrusted to our agency.

Engravings.

We have superior artists in our employ, and all facilities for producing fine and satisfactory illustrations of inventions and machinery, for newspaper, book, circular and other printed illustrations, and are always ready to assist patrons in bringing their valuable discoveries into practical and profitable use.

DEWEY & CO.,

United States and Foreign Patent Agents, publishers Mining and Scientific Press and Pacific Rural Press, 252 Market Street Elevator, 12 Front St., S. F.

Iron and Machine Works.

MACBETH'S
—PATENT—
STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys. They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq.—Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),
[Signed:] RICHARD T. MARSH,
Managing Director.

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

ST. LOUIS, Mo., Sept. 28, 1883.

Messrs. Adolphus Meier & Co., GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Patent Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER-BUSCH BREWING ASSN.

OFFICE OF Supt. OF ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 2d, we respectfully inform you that the three boilers built under your patents, under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the title caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition. (Signed): BRAUCKE.

BAKER'S MINING HORSE POWER.

THE MOST EFFICIENT AND PRACTICAL MACHINE ever invented for the service of Prospectors and others requiring the use of a Horse Power; possessing all the requirements of a first-class hoist and affording means for the continuous operation of a Pump or Blower without interfering with a hoisting apparatus.

It is made entirely of Iron; no piece weighs over 250 pounds. At the ordinary speed of a horse a 1,000-pound bucket of ore may be raised 120 feet per minute. The hoisting drum is under the complete control of the man at the shaft, and is capable of carrying 500 feet of five-eighths steel rope. The cost of erection is slight, as two men in half a day can easily put it in place ready for work.

While this power is more particularly for mining purposes, it is equally adapted to all other uses where animal power is required. SEND FOR CIRCULAR. Address

PACIFIC IRON WORKS,

Rankin, Brayton & Co.,

SAN FRANCISCO - AND - CHICAGO

MINERS' HORSE WHIM.

ONE HORSE CAN EASILY HOIST OVER 1,000 LBS. at a depth of 500 feet. The Whim is mainly built of wrought iron. The hoisting-drum is thrown out of gear by the lever, while the load is held in place with a brake by the man tending the bucket. The standard of the whim is bolted to bed-stumps, thus avoiding all framework. When required, these whims are made in sections to pack on mules.

\$1,000 CHALLENGE!

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

OVER 800 ARE NOW IN USE. Saves from 10 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the office of Hunkley, Spiers & Hayes, No. 2140 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringers.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Hand-boring Drills.

There are several forms of hand-boring drills which are now successfully used in anthracite boring, all of which are improvements on the old slate auger or shale auger, varying in details of construction. The inventions are in the method of lengthening, feeding, adjusting the crank, fastening the drill in the coal, shape of edges, etc. With any of them the miners must first hew a hole three or four inches in diameter in the face, or two or four inches high by five or eight wide, and six inches to a foot deep. The clamping bar is fastened by wedging or clamping in this hole. These boring tools have not reduced the cost of mining when performed with jumpers or ordinary drills. But it does not follow that advantages have not been derived from the use of them. It is the miners themselves who have used these machines who have received nearly all the benefits. The miners can do more work. A miner doing more work requiring certain skill will not receive more than a certain sum per day for that work, without regard to the increased amount of work improved machinery may enable them to perform, so the benefits of the system will eventually accrue to the mine operators. The miner who buys and uses these machines is benefited either by receiving pay on a larger number of ears, by finishing his work earlier, or by not working so hard as those men using the ordinary drill. Dr. Henry M. Chance, assistant geologist of the geological survey of Pennsylvania, who has had abundant opportunities for observation, states that some miners cannot learn to use these boring machines; they can neither set them properly, hold them in position until the hole is finished nor bore as quickly as with the ordinary hand drill. Others will not use them because they dislike to turn a crank, preferring a "jumper." To obtain the best results from these machines, or even to make as good time as with the ordinary drill, they must be placed in the hands of apt, intelligent and experienced miners. In the hands of a dull, slow thinker less work will be accomplished than with an ordinary drill, but a good workman can often drill his holes with the machine in half the time occupied in drilling by hand. These are some of the causes why boring drills have not more quickly replaced hand drills. These drills are commonly the private property of the miner, and before he can be induced to buy one he must be convinced not only that it will be to his advantage to own it, but he must be persuaded to abandon the spirit of conservatism common to his class.

DURING the first five months of the present year 910 miles of railroad track have been laid in the United States. During the same period fifteen roads have been placed in the hands of receivers.

Centre Crank Portable Engines and Boilers.

We present this week an illustration of a simple and serviceable form of a centre crank portable engine and boiler on skids, denominated very aptly the "New Economizer," constructed by the Porter Manufacturing Company, of Syracuse, New York.

The boilers are built especially with a view

of ensuring the consumption of a minimum

of fuel, which is accomplished by the construction of a large fire flue extending under the tubes from the rear of the fire-box to the end of the boiler, which virtually serves as an enlargement of the fire-box and consequently the heat spaces. The flames from the fire-box pass into this accessory flue, in an entire body, and in its passage the gases become thoroughly ignited before entering into the small return. The fire is entirely surrounded by water, and the front itself is so arranged as to act as a heating surface; and there being no obstruction to the draft, evaporation is necessarily very rapid. The combustion chamber is surrounded by a water jacket which protects the shell from the intense heat to which it is subjected when straw or other light fuel is used. This also gives an additional heating surface which accelerates the generation of steam. The return of the flames through the small tubes compels the deposit of nearly all of the sparks in the rear chamber, and, therefore, comparatively few are emitted from the stack. The crown sheet is guarded by the rows of tubes over it, and in the event that water should, by carelessness, become low, the tubes being first uncovered are first liable to give way before the water is so low as to leave the crown sheets unprotected. These improvements insure one of the safest forms of boilers, and the danger of fire from the

emission of sparks is almost entirely obviated.

The engines are built either with center or side cranks; they are perfectly balanced, and vibration even at the maximum of labor is reduced to a minimum. They can be run to a very high speed and are so mounted that they can be detached from the top of the boilers and placed on separate foundations and used as stationaries, and as such can be operated as either right or left hand, as the power can be

NEW ECONOMIZER, PORTABLE ENGINE AND BOILER.

transmitted from either side. The boilers and engines are thoroughly tested before leaving the works of their builders to full standard pressures and powers. They are mounted either on skids or wheels as the conditions of use may require. Mounted on skids these "new economizers" are built of a capacity of from three to twenty horse-power and will be found serviceable for pumping water, sawing wood, farm and dairy uses, running small machine shops, sewing machines and for many other purposes where small powers may be useful and required. Mounted on wheels they form agricultural engines complete for threshing and have been found very successful as straw-burners, and with a simple change of grates are equally well adapted for burning wood or coal. Larger sizes either mounted on skids or wheels are built especially for operating saw-mills, where the necessity or desirability arises of transporting portable engines and the accompanying saw-mills to the vicinage of the timber to be cut. In such events of use green wood and slabs are ordinarily the only available fuel and, therefore, the surplusage of boiler capacity and heating surface in the form herein illustrated becomes desirable from an economic point of view. Several sizes of these engines, just received by rail from their manufacturers can be seen, completely set up, at the "Joshua Hendy Machine Works," the agents in this city.

in any direction the line of least resistance leads it. Mr. MacGeorge had drawings of several mining operations in Australia in which the clinograph had accurately directed underground operations where search was being made for auriferous rock discovered by the drill. Expensive operations had been conducted on the supposition that this drill had followed a straight line, but the ore indicated was not found. The failure of one very important operation in which Mr. MacGeorge was interested prompted experiments, which resulted in the invention of the clinograph.

A long drill cannot be made to bore straight, and that is not to be wondered at considering that for a length of perhaps 500 feet the drill-rod has only a diameter of one inch and a half. It is no uncommon thing for the bore to vary ten feet laterally for every 200 perpendicular feet drilled. This in 500 feet would amount to 25 feet variation, and when the miners came to run drifts to tap the desired lode that 25 feet would cause them endless trouble and expense, for they would have to drift around in a speculative way to find their objective point. Sometimes it will go 75 feet out of the way.

The Australian Government, which has charge of nearly all the diamond drills in that country, has adopted the clinograph in its operations.

The clinograph is a new instrument for miners' use, for determining the extent and direction of deviations in long diamond drill borings. Mr. E. F. MacGeorge, of Melbourne, now in this city, has one of these instruments on exhibition at the State Mining Bureau. The instrument consists of a glass tube, about eight inches long and one inch in diameter, having at each end a glass bulb, joined by a small glass tube running through the outside inch tube. In one bulb is a delicately adjusted magnetic needle, and in the other a plummet. Both of these are freely suspended, when the whole instrument is filled with a hot solution of gelatine, in which the plummet and needle adjust themselves accurately. The instrument is then enclosed in a brass sheath and inserted any distance desired in the drill hole to be surveyed. The gelatine, cooling, hardens and fixes the needle and plummet in positions exactly indicating the direction and deviation of the bore. The instrument is then withdrawn and placed in another instrument, also the invention of Mr. MacGeorge, which marks in degrees and minutes the deviation from the perpendicular or horizontal, as the drill may have been run, and the direction of the deviation, as indicated by the needle and plummet in the solidified gelatine. The usefulness of this instrument is that in long drillings of several hundred feet the sectionalized drill very seldom follows a direct course, the fastening of the sections giving it independent motion to swerve

The New Metropolis at Coeur d'Alene.

From the Coeur d'Alene Pioneer which was lately moved from Eagle to Murray, we take the following notes of the new metropolis:

It can now well be said that Murray is the Coeur d'Alenes, for the marvelous growth of this young town has placed it beyond controversy, in the position of the metropolis of the Coeur d'Alene country. The town was laid out on the 22d day of January, and officially surveyed on the 7th of the following month. The birth of the new town attracted hardly a notice in the independent city below, and it was not to be wondered that bare whisperings of a new town was heard in March along the railway.

In the meanwhile the town grew apace. The locators had bought experience with fortune and were going to be right this time. The gold was here, and they were not long in learning that the flat where Murray now stands was in the centre of all the pay-ground that was known on the creek. The forks of two creeks was no argument against the heart of the mines. So on three contiguous claims—the Murray, Ives and Widow—on a flat about a quarter of a mile wide and a mile long, the town of Murray was laid out.

Summit District.

On the 7th of February the new Summit mining district was formed and W. H. Clagett elected recorder. The records were transferred to the new town, and at a miners' meeting a separate code of laws for the government of the district was adopted, which at once set the claims on a paying basis and compelled a fair division of the ground.

Late Events.

While the rival town of Eagle had what little capital had come into the country, and had three newspapers to shout for it, Murray gradually grew until the resources about it, which had hitherto been the life of Eagle, began to concentrate at the most convenient point. With all the boom that printers' ink can give, Eagle city could not live without the product of the country about Murray, and its decline at the rise of this town was not to be wondered at by men who have figured mining camps down to a system.

From one house in January it has grown to be larger than all the towns in the Coeur d'Alenes combined, and we can say without fear of contradiction that nine-tenths of the business of the country to-day is carried on in Murray. No place ever became so warm a favorite in so short a time, and it is with pride that Murray can thank the friends who so kindly rocked its infant cradle.

The Mines.

Murray, as we have said, is in the very center of the producing mines on Pritchard creek. In fact the town itself is on three famous claims—the Widow, Murray and Ives claims. Alder gulch, which is producing over an ounce to the man every day, comes into the town and forms one of the cross-streets.

Below the town, within three-fourths of a mile, rich gulches come in from the north—Nugget, Buckskin, Missoula and Dream. On all these pay has been found and work is actively progressing. Accounts of the wealth of these gulches have appeared in the Pioneer. Above town is Gold Run gulch, which is fully as rich as its famous namesake in California, and above this is Wasp gulch, known to contain rich ground. Then comes Cougar, Rockford and Reeder gulches, all from the north. On the last are the great

Quartz Leads.

Which are destined to be the mainstay of the camp long after placer mining shall have ceased. Experts who have visited these mines pronounce them among the most extensive on the continent. The supply of quartz is simply inexhaustible. All the way up Pritchard creek are some of the best claims known at present. The Widow, Last Chance, Butte, Sargent, Rockford, Ophir, Mother Lode and a dozen other famous properties are passed, within a distance of a mile and a half from Murray. The suburb of Butte is at the mouth of Butte gulch, and is connected with Murray by a string of cabins from 10 to 50 yards apart. On the south we have the tributaries Ophir, Idaho and Tiger gulches, and while bed-rock has not been reached in either of these, the gravel prospects very well. Thus it will be seen that fifteen side gulches put into Pritchard creek within a radius of a mile and a half. Many who have been in the Black Hills claim that the ground on the main creek alone is sufficient to make as large a camp as Deadwood.

Old Gravel Deposit.

The bar diggings are numerous, but the old gravel wash on the hills north of the town are the most extensive and the richest diggings that have been discovered in many years. The wash runs east and west, and intersects the various feeders of Pritchard creek from the north. At these points of intersection the claims have a double wash and are correspondingly rich. Several tunnels are in on the deposit, and it is certain that in more places there are several hundred feet of pay dirt. Many of the creeks can be drifted, and will therefore furnish employment to many miners during the winter months.

The Roads.

Murray has not alone these resources close at hand, but it is really the entrepot of the en-

tire country. It is the first important point reached by the Belknap and Thompson roads. Belknap and Thompson on the Northern Pacific railway are distant 28 and 30 miles respectively. A trail will shortly be completed to Carbon, and one already connects it with Eagle.

The town has a postoffice and express office, two banks, three blacksmith shops, thirteen merchandise stores, two hardware stores, saloons, three watchmakers, six bakeries, six lodging houses, two drug stores, and a host of doctors, lawyers, and others engaged in professional callings.

The present population is about 1,200 while 2,000 more are prospecting and mining in the gulches within a radius of a mile. These parties frequent the town to purchase supplies, etc. Many families comprise the population, and many more are coming. Many who are engaged in business here will soon have their wives and families, and make their homes here. This will give a stability to the country which cannot be gotten from any other source. When the sawmills are running and the wagon road completed, elegant buildings will take the place of the log structures now in use.

Mining.

Since in a single week in the East railroad stocks suffered a shrinkage greater than all the mines in the West have ever shown, we do not read any more funny stories of how New York gentlemen have kicked the men of the West out of their offices for merely offering a mine for sale. Exports fell off a few millions during the first quarter of the year, making it necessary to export some \$16,000,000 in gold, and suddenly the toy houses of the East began to totter. We wonder if some of those interested do not wish they had placed their money in Horn Silver, which is quietly paying 45 per cent per annum to stockholders, or in Ontario or in Wood River or in Butte? If the shipment of \$16,000,000 out of the country is such a calamity, then there cannot be any too much real good money in the country after all. True there is lots of wheat, a good deal of beef, any amount of pork and whisky; but somehow they are not of themselves sufficient to keep the wheels of commerce moving. Business like bread must have a leaven, and that leaven is specie. And so it comes back to the proposition which the Tribune has often advanced: that there is not another so legitimate a business in all this world as gold and silver mining. From the barren hills it draws something which all mankind covet; no man is wronged by its production; no man's property is made less valuable because of it; it speaks to the earth with a language as universal as that which was talked before the first brick was laid in Babel—all men understand it. It is, too, the same to all men. Camel drivers and kings alike respect it, and just in proportion comes loss of trade, poverty and ignorance; a falling off of charities and increase of lawlessness and vice. The horror of middle ages was due to the fact that the gold and silver of the world, had, to a great extent gravitated to the church and to the nobility of Europe, and trade, having no stimulant, faded and died. A part of the money which has been gambled off in stocks in New York, would, had it been invested in legitimate mining in the West, have returned to the investors a stream of gold. They would not see it because their eyes were dazzled. May be their visions are by this time a little cleared; a few more jolts like those they have been receiving may make them really wise. The desert holds out its arms to them, and offers them something which means \$10 or \$100 or \$1,000 for every dollar they invest. They will understand this after a while and will turn their faces this way, and those who never came will by and by learn that a dollar dug from the hills is better than any dollar obtained in any other way, for its production causes no loss to and no competition with any other business. Mining will grow in respectability now for several years to come.—Salt Lake Tribune

BERNICE DISTRICT.—A correspondent of the Reno Gazette says: The Golden Crown Company of Bernice District, Churchill county, has leased the Bothwell mill for the term of 12 months, and the mill will commence running on the Golden Crown ores on the first day of July. The company have been opening the mine for the past six months, and have now opened 700 feet of tunnels and inclines, and have completed uprisings from one level to another. The ores are free, and 100 tons was worked up to 85 per cent of the assay value by free milling process. The Wild Goose mine is being opened by the owners, and shows large quantities of high grade ores. The ores of this mine are base, and require roasting, but are high grade enough to justify the extra expense. The last 50 tons worked \$160 per ton. Quite a number of claims are being worked with good results. Among the number are the Utah, Silver Ridge, Alta and Big Chief ledges. The mill is well equipped, and has a Buckner furnace which treats the base ores successfully. There is plenty of ore now developed to run the mill for a year. The trouble between the miners and mill owners is now settled by the miners having leased the mill. This will be a steady bullion producing district for the coming year.

A LARGE number of deer forests in Scotland are going a begging for tenants.

Working Tailings.

A New Concentrating Apparatus.

An Enterprise reporter yesterday morning visited the large tailings reservoir in Six Mile canyon, just at the Sugar Loaf, where an experiment is being made by W. T. O'Neale and others in the concentration of the immense mass of tailings accumulated at that point.

The Apparatus

Was started up three days ago for trial, but it is not yet in regular operation, as the tank for holding the concentrations remains to be constructed.

That which first attracts the attention of the visitor is a large conical screen, placed horizontally outtop of a large tank. This screen is 15 feet in length. At the larger end it is 7 feet in diameter and five feet at the smaller end. The screen is made of wire cloth with fine meshes—No. 30—and is revolved by the power derived from an eight-foot water wheel that stands in the stream below.

The tailings are washed down at the reservoir by means of a hose and pipe, hydraulic fashion, and, entering a line of sluice boxes, are delivered into the larger end of the revolving screen. When the tank is full of water the large end is working under a depth of about one foot of water, while the small end does not touch the water. Inside of the screen is formed of strips of wood which resemble the thread of a screw, or rather the thread that is formed in a nut. This thread is about six inches in depth, and the pitch of it is such that any coarse stuff, as fragments of rock, bits of iron and the like, that will not pass through the meshes of the screen, is carried along through to the small end, where it is dumped out upon the ground as waste.

As the screen, for more than half its length, works under water, the weight of the tailings fed into it does not bear heavily upon the wire cloth of which it is formed. It is said that 200 tons of the tailings a day may be run through the screen, and yet the wire cloth will not need renewing for a year. As we have seen, the coarse and waste material is thrown out upon the ground at the smaller end of the screen, and we have nothing more to do with it. The fine sand, sulphurets and pulverized slickens, however, pass through the meshes and descend into the tank.

The Riffle Boxes.

By means of gates the tailings that have found their way into the tank are drawn off and pass into two lines of shallow sluices, the bottoms of which are covered with galvanized iron coated with a preparation of quicksilver. The metallic bottoms of the sluices are not flat, nor are they closely corrugated, but are arranged in the form of the long, gentle waves seen at sea—shallow troughs and flat ridges. This shape forms ripples and eddies every few inches, in which the tailings are detained and whirled about in the quicksilver covering the plate. A bit of wood thrown into these sluices is caught and whirled about in each ripple for some time before it escapes, and is caught and spun about in the next below. These amalgamated plates are useful for catching floured quicksilver and particles of gold. They are 15 feet in length and 2 feet in width. The quicksilver used is a composition, the secret of which is known only to Mr. O'Neale and one or two others. It attaches itself to iron more readily than does ordinary quicksilver to copper.

The Blanket Sluices.

After passing through the boxes containing the quicksilver plates, the tailings drop a few inches and then enter two strings of blanket sluices—sluices, the bottoms and sides of which are covered with coarse blanketing made with a long nap. It is in the nap of the blanketing that the silver sulphurets and the particles of iron pyrites containing gold are caught and held. They are much the same as ordinary blanket sluices, except that the blanketing is tacked fast to the bottoms and sides of the sluices. The blankets are not taken out to be washed, nor are they swept with brooms, as in the case of the sluices in common use. In the center the boxes rest upon a hinge, therefore may be tipped over till they stand at an angle of about forty-five degrees. A section fifty feet in length may thus be stood almost on edge. A small pipe of galvanized iron, filled with small holes, runs the whole length of these boxes, and is at the upper side where they are tipped over for washing. Water being turned into this pipe, the contents of the blankets are at once washed down into the lower side of the box, which, as it is then standing, forms a small V-shaped flume, down along which the concentrated material can be washed into the large tank provided for its reception, and from which it is taken to be worked in pans as are ordinary concentrations.

An Economical Arrangement.

The plan of washing down the tailings as they stand in the reservoir and bringing them to the screening apparatus saves all shoveling into carts or cars, and to bring the tailings to the concentrating machines costs the labor of but one man—the man that holds the hydraulic pipe. Two other men can attend to the screen and sluices. The tailings, as they lie in the reservoir, assay \$5 50 per ton. Assays were yesterday being made of the concentrations, and future operations will depend upon the results obtained from these samples. There is an immense deposit of the tailings, and from the

average assays it has been estimated that the whole contains not less than \$20,000,000 of the precious metals. If this great wealth can be saved to the world it will be a work to be proud of, and Mr. O'Neale and his partners in the enterprise will not only make a good thing by their venture but also greatly benefit this community and the whole country.

Quite a number of visitors inspected the apparatus yesterday while it was in operation, and all seemed much interested in the whole process, from the sluicing down of the tailings at the reservoir to the bringing forth of the concentrations ready for the pan or other process. The enterprise will be watched with much interest by our people.

Educational Exhibition.

The Bureau of Education of the Department of the Interior, in a recent circular, gives a list, the most of which is presented below, as indicative of what it is desired to treat in the educational exhibition to be held at the World's Fair at New Orleans in December next. It will be found to be of interest to educators, inventors, mechanics, scientists, artists, printers, professional and literary men students and others.

Plans and models of infant schools and kindergarten, orphan asylums and nurseries; system, management, furniture and appliances. Plans and models of scholastic establishments for town and country; system of management and furniture; books, maps and charts. Plans and models of scholastic establishments for adult and professional instruction. Appliances for the elementary teaching of music, singing, foreign language, bookkeeping, political economy, practical agriculture, and horticulture etc. Appliances for instruction of mutes and the blind. Specimens of the work of pupils of both sexes. Libraries and publications.

Plans and models for secondary instruction; lyceums, grammar schools, colleges, industrial and commercial schools. Classical works, maps and globes. Appliances for technological and scientific instruction and the fine arts. Gymnastics, fencing and military exercises. Telegraphy, photography and stenography.

Plans and models of academies, universities, medical schools, practical schools, technical and mechanical schools, schools of agriculture, observatories, scientific museums and laboratories. Apparatus, collections and appliances for higher instruction and scientific research; special exhibitions of learned, technical, agricultural, mechanical, commercial and industrial societies.

Specimens of topography, autographic proofs, lithographic proofs, engravings. New books and new editions of books already known, special libraries, periodical publications, drawings, atlases and albums.

Paper, card and pasteboard; inks, corks, and all things necessary for writing desks and offices. Objects made of paper. Registers, copy books, albums, account books, memorandum books; bindings, loose covers for books, cases. Various products used in water-color painting and tinting. Apparatus for the use of painters, draughtsmen, engravers and modelers.

Designs for industrial purposes. Decorative paintings, engravings for industrial purposes. Models and small articulated wooden models of figures, ornaments. Carvings, cameos, seals, and various objects decorated with engravings, objects modeled for industrial purposes, produced by mechanical processes, reductions; photostatue, casts.

Photographs, heliographic engravings, lithographic proofs, photo-lithographic proofs, photographic stereotypes, stereoscopic proofs, stereoscopes.

Wind instruments simple and wind instruments with key-boards. Stringed instruments.

Apparatus requisite for anatomical and histological work. Anatomical models and musical instruments. Apparatus and instruments for simple surgery and anesthetic apparatus. Surgical instruments and apparatus.

Apparatus for restoring persons apparently drowned or suffocated. Baths and hydrotherapeutic apparatus, gymnastic apparatus for hygienic purposes. Plans and models of hospitals, various asylums, houses of refuge, almshouses, lunatic asylums; arrangements and furniture for such establishments. Various apparatus for infirm persons, invalids and lunatics. Accessory objects for the medical, surgical and pharmaceutical services. Chests and cases of instruments and medicines for surgeons; means and apparatus for succoring the wounded on the battle-field; appliances, instruments, apparatus, and all things requisite for veterinary surgery.

Apparatus and instruments used for mathematical purposes, and illustrating practical geometry, land surveying, topography and geodesy; apparatus and instruments for measurement, optical and astronomical; physical and meteorological instruments; instruments and apparatus for laboratories and observatories, weights and measures.

Topographical, geographical, geological, hydrographical, astronomical, physical, and maps of every kind; terrestrial and celestial globes and spheres, statistical works and tables, etc.

THE production of the mines of the Hecla company, of Glendale, Montana, in 1883, was 2,602 net tons of lead, 598,472.71 ounces of silver, and 502.53 ounces of gold in the lead, and 683,695 lbs. of copper matte, containing 63,372.21 ounces of silver, and 308,519 lbs. copper,

MECHANICAL PROGRESS.

Softening and Hardening Cast Iron.

Questions have lately been asked as to the possibility of altering the texture or changing the qualities of cast iron by heating and chilling. In the respect of resistance to the superficial changes which are induced on steel by heating and sudden chillings, cast iron stands alone. It is amenable to the gradual influences of heat, but it will not contract nor harden, like steel or wrought iron, under sudden changes from heat to cold. And yet hard cast iron may be annealed, as it is done daily by tons, the heat being supplemented by the pyrogenous oxide of iron, the hot oxidized scale, such as is seen at the base of the blacksmith's anvil. It can be annealed also, if the articles are small enough, by being heated in a bituminous coal fire, and then hurried until cool in a bed of the coal shavings. This sort of annealing is entirely unlike that for hard wrought iron or obdurate steel, as in these cases only clean charcoal is to be used, any taint of sulphur being a source of injury. But in annealing hard cast iron the softening qualities of the sulphur contained in bituminous coal is what is required. Some of the most intractable specimens of cast iron, no larger in diameter than a pipe stem, that refused to yield in a genial charcoal fire when packed with bone, lime, and charcoal, softened to usable condition by one heating in bituminous coal.

As to hardening of cast iron there is no ordinary process that is generally convenient, except that of casehardening. In this the cast iron article should be polished as well as finished—the surface being made as homogeneous as can be—so that the flux of casehardening be given as large a surface for action as possible; for the composition of cast iron is a honeycomb instead of a solid; and it is not even a series of layers of fibres, as is wrought iron, or of a network of fibres as is cast steel, but it is a mass of material of which pure iron itself is not always the largest part. Recent improvements, however, have given the pure metal a preponderance over the foreign palpable matter and the air spaces. But this constitution is not common.

Even heating is necessary to caseharden cast iron; and yet the heat must be less than allowed for wrought iron and low steel, for at much less than the white heat for wrought iron or the "high heat" for carbonized steel, the cast iron would disintegrate. The cast iron should be heated to a soft red heat, and then sprinkled with powdered prussiate of potash and sal ammoniac in proportions of two of prussiate and one of sal ammoniac, and then immediately plunged into a cold water bath. It will not do, in the matter of casehardening cast iron, to return the iron to the fire, or to use the flux as a paste. Put it on as a powder, and plunge immediately into cold water.—*Scientific American*.

Corrosion of Cast Iron Pipes.

In the course of a paper read by Mr. McElroy before the Western Society of Engineers, on the causes of corrosion of cast iron pipes, the author observed that a prominent cause of corrosion is the class of materials used, and also the method of manufacture of pipes in ordinary foundries. In the first place, a cheap and easily melted pig is selected—specifications and the inspection of quality and mixture not being strict—and the castings (for convenience of handling) are generally made in greensand moulds laid at a slope of about 10 degrees from the horizontal. Impure metal is therefore run in a way that aggravates its defects. The core bars are coated with straw ropes, which may be more or less soft and loose, coated with loam, more or less soft and wet, and sprinkled with sand.

If not very carefully wedged, these bars will rise; and they are seldom stiff enough to resist the upward pressure of the molten metal. The usual spring at the center for the core of an 8 inch pipe is one-sixteenth or one-eighth inch; or as much as three-sixteenths inch with a 6 inch pipe. The metal, poured in from the upper end, first fills the lower section of the mould; and as it rises round the core to fill the upper section, its weight springs the bar upward to the extent indicated, making the casting thicker at the lower, and thinner at the upper side. The denser, hotter, and purer metal fills the lower portion; the impurities naturally floating upward to settle in the thinner metal as it cools. Here gather portions of the sand coating of the mould; while the bubbles of the metal, caused by the development of gas from the vegetable matter of the loam, and from its dampness, tend to perpetuate themselves in blisters and air cells.

The usual defects in these cheap castings are, therefore, inequality in thickness, air cells and blisters, sand holes, cold chutes from chilled metal, and mixtures of sand and iron. Such pipes are also frequently out of line, from the effect of unequal contraction. Pipes of this description are peculiarly liable to corrosion; containing as they do mixtures of metal of different densities, together with much graphite. The duration of such pipes in the ground is largely affected by the amount of disturbance they receive. If well laid at a good depth, and thoroughly backed, they may continue serviceable for many years; but their defects are likely to become suddenly prominent upon comparatively slight external interference. In

favorable circumstances they may last more than 30 years; but the majority if tested after less use will show flaws that would have insured their rejection if detected when new.

RAILROAD PROGRESS.—When the New York and New England railroad was built, engines with but two drivers were used exclusively, on the supposition that more could not be employed, because of the great number of curves. In course of time, however, the fallacy of this belief was shown, and now it uses consolidation engines of enormous proportions. Thus, one by one have passed away erroneous notions with reference to important mechanical facts connected with the operation of the railways of this country, giving to the traveling world increased safety, speed and comforts more rapidly than it is possible for the average mind to appreciate. In this connection we may also remark that the wonderful growth in this country of facilities for the manufacture of rails during the past few years is forcibly illustrated in the fact that for several days recently the Edgar Thompson Steel Works of Pittsburgh turned out over 700 tons of steel rails every day. At this rate, supposing the rails to weigh 56 pounds per yard, this one mill could produce in a year rails sufficient for about 2,500 miles of track. And this is but one of a large number of mills, several of which are doubtless able to turn out very nearly as large a product as that referred to. Certainly there is no immediate prospect that the railway interest of the country will require any addition to the present capacity for producing rails.

ALTERED ENGINE IMPROVEMENT.—A Cleveland (Ohio) man claims to have invented an engine which gives a working pressure in the cylinder of four pounds above the pressure in the boiler. It has two steam chests placed on the opposite sides of the cylinder. He claims that a trial made with one steam port and chest open gave as good results as could be obtained from an ordinary engine, and by turning on the steam on the opposite side a gain in power was made of fully fifty per cent. This result, the inventor says, can only be accounted for by the concussion of the two currents of steam coming together from opposite ports, or by the liberation of latent heat not heretofore utilized by the old way of applying steam to the cylinder. This improvement can be applied to an ordinary engine by changing the cylinder and valve gear.

GLASS BEARINGS.—To what purposes may not glass be put? Bearings made of glass are now being experimented with in the rolling stock of railroads in regard to their frictionless qualities. This material is a hard, clear substance, and must wear down smooth and give a fine bearing surface for an axle to rest upon. It is a non-conductor of electricity, if not of heat, and the fine particles have as good a chance to work down the bearings of the axle to a running fit as in the grinding in of a valve seat for a brass valve, and much power is expected to be saved by converting the wearing of a journal into some other agency, than by converting it into heat.

THE FUEL COST OF HIGH SPEED.—Some experiments have recently been made upon the Pennsylvania road, near Philadelphia, to ascertain the difference in the consumption of coal between running a train very rapidly and at a very low speed. The same conditions, same number of cars and similar engines were employed. The trains in each case run the same distance—119 miles out and back. Some stops were made. The fast train ran on schedule express time. The slow train ran at the tunnel pace of twelve miles an hour. The fast train consumed 6,725 lbs. of coal. The slow train consumed 4,420—saving effected 2,305 lbs.

SOLID DRAWN STEEL TUBES are made in England and imported upon order. They are quite smooth and straight, both inside and outside, and will stand great pressure. Most of the demand is for hydraulic purposes. The importer of these tubes informs us that the largest size now made is 4½" outside and 4" inside diameter, and this size costs \$5 a foot. The demand is increasing, and the works run day and night. A very large amount of money was spent in experimenting before the process was made entirely successful.

IMPROVED BOILER TUBES.—In order to obtain the greatest possible efficiency in the steam-heating surface of boilers, a new kind of vertical steam boiler has recently been invented by a Mr. Armer. To obtain this efficiency, the boiler tubes have a helical twist given them, which does not interfere with the ease with which they may be cleaned, but which causes greater impingement of the gases against the tube walls, and gives more freedom for expansion than straight tubes.

A CORRESPONDENT in *Engineering* refers to the small amount of power absorbed in engine and pump friction in the published tests of American pumping engines, and hints that the reason may be due to the internally packed pump plungers, by which leakage cannot be readily detected. Equal results he says are never reached in England, and thinks there is something of the "white elephant" about them.

SCIENTIFIC PROGRESS.

Colors Produced by Photographic Printing.

An engraver and amateur photographer of Paris recently announced that he had discovered the art of taking photographs in colors, and asked of the Minister of Instruction for a grant of money to make his invention public. Quite an interest was excited both in scientific circles and among the public, and the inventor was invited to give a public exhibition of his work in the presence of the Minister and several scientific and photographic experts. The latter reported as the result of their observations and investigations that the inventor had not succeeded in reproducing natural colors by photography; but that being only an amateur he had probably deceived himself and produced simply a combination of mechanical and chemical results, which is quite interesting and is described by a Paris correspondent as follows:

Take a negative of a picture, print the image very slightly upon salted paper—that is to say, paper prepared with a chloride and then sensitized upon a silver nitrate bath. Upon this skeleton of an image must be painted the colors of the original picture, and that as similar as possible. The colors to be used must be those mixed with albumen. Such colors are sold in England under the name of "moist colors." When the coloring is completed the paper is floated upon a solution of albumen salted with a chloride. When dry the paper canvas, or other material is sensitized upon a silver nitrate bath, and when dry it is placed in juxtaposition upon the negative. The photographic image is now fully printed out, as in an ordinary silver print. The image is then plunged into a solution of hyposulphite of soda, and when fixed it is well washed and then dried. All the colors can be seen through the albumen, the photographic image giving the half-tones and shades—in all presenting a very pretty appearance, and quite capable of inducing any one to cry out "Wonderful!"

This is the history of photography in natural colors which has made so much noise—not only in scientific circles, but also among the public—during the last few days.

LIQUID CARBONIC ACID.—It appears, as a result of the labors of Dr. Raydt, of Hanover, that liquid carbonic acid is speedily destined to take its place as an article of commerce, susceptible of important chemical and mechanical applications. The liquid is contained in wrought iron or steel cylinders, holding 10 liters, in which this quantity of liquid, under a pressure of 36 atmospheres represents 450 times its bulk of gas. Dr. Raydt's improvements comprise not merely the commercial production of liquid carbonic acid, but also relate to the arrangements for disengaging it at a regulated pressure. When the price of this liquid is sufficiently low, it will find many uses wherein great pressure is required to be applied within a small or confined space. At Krupp's Steel Works liquid carbonic acid is used to compress cast steel while cooling in moulds. For this purpose, by heating the reservoir of liquid to 20° C., a pressure of 1,200 atmospheres has been obtained. In this form also pure carbonic acid in considerable quantity, for chemical purposes, may be easily stored and transported.

THE PRESENT LIMIT OF MICROSCOPIC VISIBILITY.—Although there is perhaps much to be desired in the improvement of microscopic objectives, we may still consider our present state quite an advanced one. Although the present theoretical limit of visibility is fixed at 146,528 lines to the inch, we need not be deterred from attempting to pass this point. The limit which was accepted some years ago as the true one, although considerably lower, was quietly ignored as the angular aperture in objectives increased. It is only a few years ago that the majority of microscopists refused to believe that *A. pellicida*, which has about 100,000 lines to the inch, could be resolved, and now it is the work of beginners to do so. But supposing 146,528 lines to be the limit, it is evident that a one-eighth or one-tenth objective with a one-half inch eye-piece is of amply sufficient magnifying power to make the lines visible to the eye, and there is therefore no need of using more. It is a good rule to follow, under all circumstances, not to use a greater power than is necessary to comfortably do the required work.—*A. Bausch*.

PURIFICATION OF WATER BY MOTION.—A discovery has been made by Dr. Pehl, of St. Petersburg, which promises to have a very important bearing on many industrial processes. The water of the river Neva is very free from bacteria, having only about 300 germs in a cubic centimeter. The canals of St. Petersburg, on the contrary, are infected with bacteria, their number reaching 110,000 in a cubic centimeter, even during good weather. The same is true with regard to the contents of water for the supply of the city. While the chemical composition of the water passing through these conduits hardly differs from that of the Neva (by which they are supplied), the number of bacteria reaches 70,000 against 300 in the water freely taken from the river; and the worst water was found in the chief conduit, although all details of its construction are the same as in the secondary conduits. Dr. Pehl explains this anomaly by the rapidity of the motion of the water, and he

has made direct experiments in order to ascertain that. In fact, when water was brought into rapid motion for an hour, by means of the centrifugal machine, the number of developing germs was reduced by 90 per cent. Further experiments will show if this destruction of germs is due to the motion of the mass of water, or to molecular motion. If this discovery of Dr. Pehl is confirmed, it will become possible to destroy bacteria, and render a water comparatively pure, simply by passing it through a centrifugal machine. The subject is of special interest to brewers, who suffer, perhaps, more than any other manufacturers, from the attacks of bacteria.

MAGNETIC FRICTION. The peculiar circumstance that in certain dynamos the cores of the electro-magnets gradually heat up, their temperature continuing to rise even after the machine has stopped working, has led to some interesting experiments recently conducted by two German scientists, Messrs. Warburg and Honig. A number of explanations have already been offered for this peculiarity, none being that the draft created by the machine when working keeps the temperature down by carrying off heat, whereas when the machine stops the draft ceases. It has been argued, on the other hand, that the Foucault currents, or the magnetic friction causing heat, do not cease to operate on the stoppage of the dynamo, and the result of the investigations just mentioned seem to indicate that the heat is mainly due to magnetic friction. In carrying out the experiments a core of iron was carefully magnetized by a coil, and the heat generated was measured in an ice calorimeter. If the heat depended only on the electrical resistance of the iron to the circulation of the Foucault currents, and if the coercive force of the iron was zero, Messrs. Warburg and Honig argued that they could calculate the heat generated by two cycles of magnetization. The calorimeter, however, showed a different result, and it was concluded that nearly 75 per cent of the heat was due to magnetic friction.

THE GREAT SPOT ON JUPITER.—In a recent report of Prof. G. W. Hough, the director of the Dearborn observatory, to the Chicago Astronomical Society, that gentleman among other things says that the recent spot on Jupiter, which has attracted so much attention from astronomers and others, is not the first time such a phenomena has been noticed on that planet. In the years 1664, 1665 and 1666, a great spot, with a diameter of some eight thousand miles, or about one-tenth that of Jupiter, was observed by Hook and Cassini, and situated in latitude 6° south of the planet's equator. The spot reappeared and vanished eight times between 1665 and 1708, was invisible from this latter year until 1713, and the longest period of its continuous visibility was three years, and of its disappearing, five. Professor Hough suggests the possible identity of that great spot with the present one, taking much the same ground with Russell, of Sydney, that it is a portion of the solid body of the planet, or *Jupiter firmus*, so to say, and when not seen is simply rendered invisible by a covering of clouds.

THE AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE will hold its annual meeting this year at Philadelphia. The British Association holds its meeting at Montreal, just previous to the Philadelphia meeting, and it is expected that many of its members will attend at Philadelphia meeting, which will no doubt have one of usual interest and value, so much so that Congress will in some way facilitate the active participation of the several government scientific bureaus. Interesting and valuable contributions from European sources are confidently expected.

OIL USED TO QUIET THE WATERS AS EARLY AS THE SIXTH CENTURY.—M. Henri Parville, in the *Paris Debats*, quotes a reference to the singular action of oil on waves by Theophrastus, the Byzantine historian of the sixth century. As the wind, he says, is a "subtle and delicate thing," and oil is "adhesive, unctuous and smooth," the wind glides over the surface of the water on which oil has been spread, and can not raise waves.

CURIOSITIES OF MAGNETISM.—If an iron wire be twisted during or soon after the passage of a voltaic current through it, the wire becomes magnetic. When the wire is twisted in the manner of a right hand screw, the point at which the current enters, becomes a South pole; in the opposite case it becomes a north pole. If during the passage of the current, the wire be twisted in different directions, the polarity changes with the direction of the twist.

PURITY IN METALS.—The characteristic sign of purity in metals is the power of crystallization; the purer the metal the more ready and perfect the crystallization, and the less its cohesive strength. Zinc, when quite pure can not be rolled into sheets, but when mixed with a small percentage of lead, it becomes very ductile. Gold has to be alloyed with copper or silver to make it suitable for use in arts or commerce.

A NEW GOOSEBERRY.—Three new species of flora are reported to have been discovered by Rev. E. S. Green, a botanist of Santa Barbara. In the Middle of San Luis Obispo County he has also discovered a new species of gooseberry wholly unknown to science. Near Soledad he came upon a new species of olive tree, peculiar to California.

THE *Coeur d'Alene Eagle* says it is positively no exaggeration to say that every gulch in a radius of ten miles from Eagle yields fair prospects, while many of them are very rich.

The Government of the United States never intended to make any money out of the Patent office. No money is received for its support or maintenance, from taxation. Every dollar is paid by those who have business with the office—the inventors of the country. In view of the large surplus, and the fact that the inventors pay for their work, it seems too hard that the business of the office should be trans-

A Lode Claim Within a Placer Patent.

A very important decision has been rendered in the Supreme Court of the United States, to the effect that in an action by the patentee of a placer claim to recover possession of a lode within its boundaries, where the lode was known to the patentee at the time of applying for the patent, and he did not include it in his application, he is precluded from any right of possession of the vein. The action was brought by the Iron Silver Mining Co., owning the Wells and Moyer placer claims in Colorado, against Sullivan and others to secure possession of a lode on the placer claim.

The Government, when it issued the patent to the Wells & Moyer claim, gave the veins or lodes which might thereafter be discovered, but expressly excepted and excluded them from rights of any lodes then known to exist. The amended answer to the complaint alleged "that at the time of the location of the placer claim and application for the patent, a silver lead lode was known to exist under the surface of the placer claim." The defendants claimed that the failure to include this vein in the application of patent by the complainants amounted to a conclusive declaration by the patentees that they made no claim to the lode.

The defendants went on the land on January, 1883 the placer patent issuing on January, 1879 and located the vein, complying with the legal requirements of posting notice, marking surface, etc. The defendants therefore claimed the vein.

The plaintiff denied their statements, and said that the lode was not located before the placer patent was issued, nor had it even been discovered at the time, but that the defendants located their lode claim within the boundaries of the patented ground after the issuing of the placer patent; and because the applicants for the placer patents were not required to apply for the vein or lode claim unless it had been duly discovered, located and recorded, it was owned by the applicants for the placer patent at the time of applying for the patent.

The Circuit Court in Colorado, sustained the demurrer to the amended answer and gave judgment for the plaintiff, and the defendant sued out the writ of error.

The case was appealed to the Supreme Court of the United States. The whole case had to be decided under section 2333 of the Reserved Statutes, which defines the question of lodes in placer claims.

The counsel for both parties in their arguments discussed the question whether a vein or lode included within the boundaries of a placer claim, the application for which does not include an application for the vein or lode claim, is excepted out of the patent for the placer claim, if at the time of the application it is known to the applicant to exist, but no claim to the vein or lode has been located.

In accordance with the view expressed by the Circuit Court in the opinion delivered on sustaining the demurrer to the original answer, the defendants in error maintained that by virtue of section 2333, taken in connection with 2320 therein referred to, a vein or lode within the boundary of a placer claim is not excepted from a patent for the placer claim for the vein or lode had previously been located according to section 2320.

The plaintiffs in error contend, that if the existence of the vein or lode is known to the applicant for a placer claim, he must include in his application for the placer claim an application for the vein or lode claim, and pay for the latter at the higher rate, in order to obtain any title to it.

The Circuit Court treated the question of the construction of this statute as one of much difficulty and of some doubt, and as affecting numerous cases. The Supreme Court should not express an opinion upon it unless its determination is necessarily involved in the adjudication of the case at bar.

The Court said: We are of opinion that the question is not presented for adjudication by the record before us. The amended answer alleges that at the times of the location and survey of, entry upon, and application and patent for the placer claim, the lode or vein was known to exist, and was claimed to exist, within the boundaries and underneath the surface of the placer claim, and the fact that the vein was claimed to exist and did exist within the premises, is and was known to the patentees of

that claim. The phrase, "claimed to exist," as used in the amended answer, apparently intending to follow the form of patent therein set forth, is not, indeed, a statement that a claim for the vein or lode has been in due form made and located, but only that it was contended that the vein or lode existed. But the further allegation in the answer that the vein was known by the patentees to exist at the times mentioned, is an allegation, in the very words of the statute itself, of the fact which the statute declares shall be conclusive against any right of possession of the vein or lode claim in a claimant of the placer claim only.

Whether the words "known to exist," as used in the statute, are satisfied by actual

Daily Inspection of Mines.

The periodical inspection of the hoisting appliances on mines is not by any means neglected among us on this coast, where the ropes are carefully attended to and examined by competent men, specially detailed for the purpose. But we have no government regulations on the subject or state laws, and the matter is left pretty well to the superintendent himself. In the large mines it is more neglected, though in smaller ones daily inspection is not carried out as a general thing. In Great Britain the laws require the working places of coal mines and the roadways leading thereto to be examined, before they are entered by the workmen. The inspectors have been trying also to

vogue for at least 11 years.—Mr. Arthur Henry Stokes, Assistant Inspector of Mines, said that he did not consider an inspection of the mine five hours before the shift was sufficient to ensure the safety of Shireoaks Colliery. He had inspected it for 11 years, and he considered it a fairly ventilated one. He considered it a physical impossibility for a man to properly examine 10 miles of roads and workings, as the deputies had to do here.—Mr. Walter Salmon, managing director of the Plaxton Colliery, said their pits were examined every two hours, but they worked with naked lights. Mr. Fred K. Channer, certified agent for the Butterley Company, said that in their collieries, numbering 27, they inspected within two or three hours of the commencement of work. Mr. Joseph Humble, manager for the Staveley Company, said they got about 900,000 tons of coal per year, and they examined within three hours of the commencement of the shift, and found no practical difficulty in doing so.

The defense contended that inspections at Shireoaks had been made in compliance with the second general rule, and that the Act did not record any special time limit, and therefore no time limit could be imposed.

The summons charged Mr. Wright with not having on a particular day inspected the mine with safety lamps before the men went to work, but the witnesses called in support of the case proved that they did inspect. The deputies told the Court that they examined one place five hours before the men went to work.

It was not a question of economy, as the management were willing to adopt every precaution necessary for the safety of the men. It was their contention that if this theory of inspection were carried to a great extent further it would entail much more serious evils than those they were endeavoring to cure. It was finally decided that as long as the mine was inspected the law had been complied with, and that the inspectors could not force the mine owners to any specified time for examination.

Academy of Sciences.

A meeting of the Academy was held on Monday evening last, Dr. H. W. Harkness in the chair. A twelve-pound fish, *Seriola oblonga*, caught off Monterey, was presented by A. Paladini. Rev. Edward L. Greene presented specimens of a new flowering plant collected by himself last April, on Tulare plain. It is a new generic type and is now named by Mr. Greene, *Crockeria chrysantha*, in honor of Mr. Charles Crocker, in recognition of his generous patronage of California botany. Dr. H. Hermann Behr, spoke of the army worm, comparing endemic with epidemic insects, and exhibited moths and germs caught in this State. The introduction of the European sparrow, which preys on insect-feeding birds and insects, has done us great injury, by allowing pests to multiply among us. Professor C. A. White, of the United States Geological Survey, now engaged on this coast in paleontological explorations, said the English sparrow drives off native birds, and its introduction anywhere is unfortunate. He said great activity now exists at Washington in every branch of science, and the whole country is awake. Paleontology is a continuation of zoology and botany, reaching back into the age of fossils. Washington has now become the great centre of biological science of the world. The United States Fish Commission is doing much excellent work, and the U. S. S. *Albatross* has just returned from her first cruise. The United States steamer *Fish Hawk*, is also at work.

Indian Signals.

In the Press of February 2d we made an extract from the publications of the Bureau of Ethnology of the Smithsonian Institution, and gave an engraving of a form of Indian signaling. That represented an Indian giving the signal of discovery or alarm.

These signals are actions of manifestations intended to be seen at a distance, and not allowing the minuteness or detail possible in close converse. Signals may be executed, first, by bodily action; second, by action of the person in connection with objects, such as a blanket, a lance, or the direction imparted to a horse; third, by various devices, such as smoke, fire or dust, when the person of the signalist is not visible. When not simply intended to attract attention, they are generally conventional, and while their study has not the same kind of importance as gesture signs, it possesses some peculiar interest.

The engraving given herewith is a representation of a signal of peace or friendship. The hands, with open palms, are elevated over the head. This signal, meaning "No Arms," was first noticed by Dr. Hoffman in 1871 in northern Arizona, and is used by the Apaches, Mohaves, Wallapais and Seviches.

Aside from its ethnological interest the engraving is of general value as giving a glimpse of the peculiar vegetation and the topographical features of the Arizona landscape.

INDIAN SIGNAL OF PEACE OR FRIENDSHIP.

knowledge of the applicant, or imply also a located claim for the vein or lode, the same meaning must be attributed to them in the amended answer; and the fact signified by the statute is well pleaded, for by the elementary rules of pleading, facts may be pleaded according to their legal effect without setting forth the particulars that lead to it; and necessary circumstances implied by law need not be expressed in the plea. In order to present the issue discussed in argument, the plaintiff should either have traversed the allegation or have replied that no claim for the vein or lode had been located at any time in question.

We find nothing in the statutes of Colorado which changes the rules of the common law in this respect. The judgment must therefore be reversed, and the case remanded to the Circuit Court, with liberty to either party to move in that Court to amend pleadings.

G. F. WILLIAMS, formerly Superintendent of the Spring Valley hydraulic mine at Cherokee, in this State, has left for London en route to South Africa, to take charge of gravel mines there. It is said his salary is to be \$15,000 a year. Mr. Williams is a talented young mining engineer, son of the late A. F. Williams, of Oakland. His experience in California will be of great service to his employers in Lydenberg district, Transvaal.

have this examination made not more than two hours before the miners enter. In a recent case the manager of the Shireoaks Collieries, was summoned at the instance of Her Majesty's Inspector of Mines for the Midland district, for not having the workings of his colliery inspected within a reasonable time of the commencement of work on March 14th and 31st in accordance with General Rule 2, whereby he was guilty of an offense against the Act, and had become liable to a penalty. It appears that towards the close of last year, Mr. Evans, by order from the Home Secretary, sent a circular letter to the colliery proprietors in the Midland district, requesting them to have all the workings inspected within four hours of the commencement of work. A meeting of the proprietors was held, at which a resolution was passed strongly condemning this circular, and protesting that it was unnecessary to accede to its request. The present case, therefore, was regarded as a test case, and great interest was centered in the proceedings, gentlemen connected with the mining interest being present from all parts of Yorkshire, Derbyshire, and Notts.

On behalf of the Government Inspector it was contended that the Act had not been complied with, and called the deputies from the collieries, who proved that in the case of some of the workings an inspection had not been made within five hours of the commencement of the shift; but in others an inspection had been made immediately before the workmen entered. They also stated that this system had been in

Borax.

Production.

The following table shows the annual and total production of refined borax made in California and Nevada during the past ten years:

	Pounds.	Pounds.
1873.....	2,000,000	1,584,966
1874.....	4,000,000	3,860,748
1875.....	5,438,658	4,045,405
1876.....	5,180,810	4,236,291
1877.....	3,727,290	
1878.....	2,802,800	36,871,958

Adding to the above an estimate of 1,000,000 pounds, made prior to 1873, gives a total, to the close of 1882, of 37,871,958 pounds—equivalent to 18,935 tons of 2,000 pounds each.

The census authorities reported the product for the year ending May 31, 1880, as follows:

	Quantity, Pounds.	Value.
California.....	1,422,443	\$107,333
Nevada.....	2,270,000	169,900
Total.....	3,692,443	\$277,233

Of the production made in 1882 the quantities produced at the different leading refineries were as follows:

	Pounds.
The San Bernardino Company.....	1,540,000
The Teel's Marsh Company.....	2,099,539
The Pacific Company.....	251,000
The Nevada Company.....	82,200
Various small companies.....	263,552

The borax made in this country finds its chief market in London and New York. Small lots are also exported to Germany, China, Japan and various other countries, and of these the larger portion goes to Germany.

Exports.

The shipment of borax by sea from San Francisco in 1882 were 1,053,856 pounds, valued at \$114,310.21.

In 1882 there were 998,578 pounds carried east by the railroads.

The domestic receipts of borax at San Francisco in 1882 were 4,236,291 pounds. The domestic receipts of borax at San Francisco since 1876 is as follows:

	Pounds.	Pounds.
1882.....	4,236,291	2,663,000
1881.....	4,000,200	3,530,300
1880.....	4,008,600	3,143,000
1879.....	1,038,400	

Composition.

An analysis of a sample of California refined borax, from San Bernardino county, the production of the San Bernardino Borax Mining Company, was made by Mr. Edward Booth, for the California State Mining Bureau. It is as follows:

Borax—Water, 47.05; biborate of sodium, 52.80.....	99.85
Chloride of sodium.....	Trace.
Sulphate of sodium.....	Trace.
Insoluble residue.....	Trace.

An analysis by the same chemist was made of a sample of concentrated borax from the works at Esmeralda county, Nevada, and of the insoluble residue which interferes with its crystallization, as follows:

Borax—Water, 46.25; biborate of sodium, 52.68.....	98.93
Chloride of sodium.....	.50
Sulphate of sodium.....	.25
Insoluble residue.....	.38

The insoluble residue consists of—

Water.....	9.00
Organic matter.....	6.40
Silica.....	73.32
Sesquioxide of iron.....	1.42
Lime.....	3.87
Soda.....	5.51
	99.52

History of the Borax Industry of the Pacific Coast.

In considering the industrial and commercial history of borax on the Pacific coast, it is found that it has been marked by disappointment and loss almost from the first. Prior to any production being made in Nevada, the price of this salt ruled everywhere at 28 to 35 cents per pound, figures that held with but little variation up till 1872, when the price dropped during the next two years as low as six and a half cents in the San Francisco market. After touching this low figure the price of refined borax underwent some slight improvement and advancing slowly, reached, about two years since, present rates, 11 to 13 cents per pound in New York, the controlling market in the United States. This sudden extreme, and long-continued depression in the price of borax was due to the following principal causes, not to mention others of minor import:

As did the Pioneer Company in California, so did their successors at a later period greatly over-estimate the extent and richness of their deposit, as well as the rapidity with which the original stock, when removed, would be likely to replace itself. Spreading abroad, these exaggerated reports caused the foreign dealer, fearing an over-production, to buy sparingly, a course that soon began to work a reduction in prices. The manufacturer, alarmed at this new arrival in the field, began also to mark down the prices, making arrangements to enlarge his production at the same time, and thus the market became badly demoralized before these salines had as yet made any large output, or any over-production had actually occurred, this latter, in fact, an event that never came to pass. Meantime, the Nevada producers met with disappointment on every hand. Their deposits were by no means as fruitful as they had anticipated. Being inexperienced in the business,

they failed to put their borax upon the market in presentable shape, from which they suffered some discredit. The product of their refineries was disposed of hastily, and through such diverse channels as soon placed them in the attitude of mutual competitors, the hope of each company that they would, through the superior excellence of their deposits or their sharper management, be able to undersell their neighbors, having prevented them from entering into any concerted action. Having been persistently kept up, these evils and errors developed such obstacles as, in the course of a few years, forced everyone of these companies to greatly curtail or wholly suspend operations; the production of borax on the Pacific coast having fallen off before the end of 1879 more than 70 per cent from the largest amount previously made. With some advance in the price that took place in 1880, several works started up again, others having followed as prices further improved, until the present complement was got under way.

In calculating their chances for success, the Pacific Coast manufacturers made the double mistake of overestimating their own and under-estimating the resources of foreign producers. It was supposed by these novices that the previously prevailing high prices of this commodity the world over were due to a scarcity of the raw material, or the difficulty of obtaining it in the countries where the principal supply was drawn—a manifest error, inasmuch as the borate deposits of Europe, India and Peru, at the time the new industry was striving for a foothold on the west coast of the United States, were ample to meet all the requirements of commerce the high prices that had always before obtained being the result of well-perfected combinations through which the entire business was controlled by a few persons, who, besides controlling the trade, were able to supply any increased demand that might arise, and do so at reduced prices, were this necessary. These parties were therefore in a position to become dangerous competitors of any new rival entering the field.

The manufacturers of borax on the Pacific coast labor under many disadvantages as compared with producers elsewhere. Labor and other factors of production are dear; the borate fields are located in desert regions, which afford few facilities for carrying on the business of refining, being at the same time distant several hundred miles inland from San Francisco, the principal entrepot and shipping point for the entire country. After shipment at San Francisco the borax has to make long journeys by sea or land to reach the great marts of the world.

The recent discovery of heavy deposits of borax near the Sea of Marmora, Asiatic Turkey, has also had a depressing effect.

Wages, Etc.

The following statement of expenditures made by the San Bernardino Borax Company on account of labor and supplies for the month of March, 1883, fairly represent expenditures of the other borax companies, both in California and Nevada, on account of these items:

WHITE LABOR.			
Employees.	Wages.		
	Per day.	Per month.	
Clerk at mine.....		\$125 00	And board
Agent, (Mojave).....		100 00	Do.
Blacksmith, 1st.....	\$5 00		Do.
do, (helper) 2d.....	3 00		Do.
Engineer.....	4 00		Do.
Teamster.....		100 00	Do.
Swampers.....	1 95		Do.
Fuel teamster.....	3 25		Do.
Coopers.....	3 25		Do.
Boilermen.....	2 31		Do.
Watchmen.....	2 31		Do.
Laborers.....	1 95		Do.
Cook.....		50 00	Do.
CHINESE LABOR.			
Foreman.....		50 00	No board.
Laborers.....	1 25		Do.

At cost of \$1 per day.

Total white labor list, 25 men, 31 days, March..... \$1,804 96
Total Chinese labor list, 35 men, 31 days, March..... 1,400 03

Total monthly expenditure for labor..... \$3,204 99

The forage consumed during the month of March, 1883, at the works of the San Bernardino Borax Company, was as follows:

Horses and Mules.	Hay.		Barley.		Total Cost.
	Pounds.	Value.	Pounds.	Value.	
2 large teams, 40 animals...	10,050	\$228 71	19,595	\$391 90	\$620 61
35 animals...	15,900	213 75	15,636	312 72	526 47

REMARKS.—Fifty cents per day cost per animal; two transportation teams; 85 miles wagon haul. Teams at the works.

The average monthly wages in borax manufacture in Nevada in May, 1883, were as follows: White laborers, \$45 and board, which is equal to \$75; Chinese, \$40, board themselves; superintendents, \$60 to \$75 and found; teamsters, \$50 to \$60 and found; blacksmiths, \$75 and found; mechanics, \$75 and found; engineers, \$100 and found; firemen, \$50 and found; tinsmiths, \$75 and found.

The Eastern Market.

Inquiry among refiners and dealers in New York city, developed the fact that the domestic borax is generally preferred to that imported, being usually superior to corresponding grades. For jeweler's uses, however, English refined borax has been imported. The chief impurities

in the American borax are organic substances, and excess of water and soda. For many uses the refining is rather to produce a better-looking product than because of absolute necessity. Refining consists simply in dissolving the crude or half refined borax in water, settling, and slowly recrystallizing.

The leading uses of borax are in welding (for which the greater part is consumed, in iron and steel manufactures); in refining metals, as a crucible flux; in enameling; by packers, in preserving meats; and as a detergent for household purposes.

The price of American borax in New York at the close of 1882, was as follows: California refined, 13½ cents; New York refined, 13½ to 13½ cents; crude 10½ to 11 cents.

Tinical, (crude borax) comes from the neighborhood of Calcutta, India; crude borate of lime from the west coast of South America; boacic acid from Tuscany. Refining is carried on to a considerable extent in England.

Tariff.

The new tariff rates are as follows: Refined borax 5 cents per pound; pure boracic acid, 5 cents per pound; commercial boracic acid, 4 cents per pound; borate of lime, 3 cents per pound; crude borax, 3 cents per pound.

Snake River Placers.

Placer mining being the great industry of this portion of Idaho, it is proper to give the points on this subject. The Independence mining district, situated near Minidoka, or fifty miles east of Shoshone, shows signs of more vigorous action this summer. The Hamburg Bar Company, ten miles southeast of Minidoka, employs two men, and as soon as the river ceases rising will begin concentrating and retorting their product. This mine is the oldest in the district and its product is of the finest, assaying 960 fine.

The company will use Heuschkel's process on their black sand, and a new water motor for filling their sluices from Snake river. Coming down the river the next mining property belongs to the Boston Placer Mining Company on the south side of the river. The active operations of this company are at present confined to their upper properties at Bonanza Bar, thirty miles above. Mr. S. D. Gilbert, the President, is now figuring on putting up one of the new motors of which more will be said hereafter.

Superintendent Goddie, of the Midas Mining Company, has received a No. 12 Heald & Sisco centrifugal pump and is only awaiting the subsidence of the river to put it in position. This pump will be operated by a fifty horse-power engine and sixty horse-power return flue boiler, which will supply about 900 miners' inches of water. The work of this company promises to be on a gigantic scale this season. Its ground is very fair and will produce, when properly worked, a large quantity of gold. The Idaho Mining and Development Co. has a very fine bar just below the Midas. Its machine will be operated by water raised from Snake river by an improved automatic motor, the invention of Job Smith, of Utah. This machine is on floats with a scaffolding as high as it is wished to raise the water. A series of floats forming a water wheel (axes on the periphery) is set in motion by the current of the river, thus operating an endless link-belt to which are attached floats on the principle of the chain pump. The water is drawn by those floats into a pump tube extending from beneath the river level to the height it is desired to raise the water. Once in operation, this machine is run by the river, thus costing nothing to run it. Its construction is so simple that the initial cost covers everything and its capacity for raising water is only limited by the size of the pump tubes and the dimensions of the motor, thus fitting it for operation on those high rich bars on the river hitherto inaccessible to miners on account of the difficulty in procuring sufficient water. A careful study of this machine and its capabilities will show its usefulness for irrigating as well as for mining. Messrs. Baker and Ludge, of Minidoka, are the owners of the right for the Territory of Idaho, both for mining and agricultural purposes, and they hope through the agency of this powerful and economical motor to see the irrigating canal for cultivation meandering its peaceful way along both banks of the Snake river for many hundred miles before another decade shall have passed. This seems certainly a feasible project, and vastly cheaper than to obtain irrigating facilities by diversion. The Vulcan Company next below the Idaho Company's grounds, is idle for the present, although it has machinery and a mill, only awaiting the word "go" from Mr. Davis, the owner in Obeyenne. The water is higher in Snake river by six inches than it was last year, and with heavy rains nearly every afternoon the water is still raising.—*Idaho Statesman.*

AN IMPROVED ORE CRUSHER.—In Utah there is said to be an improved crusher just out—an improvement on Blake's—that will crush one ton per hour so that it will go through a 45 screen—fine enough for leaching, and probably for roasting and amalgamating. The wearing parts of this crusher can be furnished for \$250 a year, and it steadily at work. These improvements promise an immense reduction in the cost and maintenance of ore-reducing plants, in the cost of extracting the precious metals, and consequently the rendering available of many ores heretofore worthless by reason of their poverty.

Spring City Notes.

A correspondent of the *Silver State* says: The Paradise and Wild Goose mines, under the superintendency of J. V. McCurdy, and the foremanship of T. D. Soper, have been opened up and developed in a systematic and skillful manner and show conclusively that all that is required to make this one of the most prosperous mining locations in the State is to put the right man in the right place, and that others of our mining camps in this county, which have almost been abandoned, might prove valuable. It may be said that the Paradise mine was virtually abandoned for several years and pronounced worthless by some of the company's former superintendents, who were undoubtedly better mining men when sitting about an office stove in the city than when in the mountains; but Mr. McCurdy has demonstrated beyond a doubt to the mind of any reasonable man that the mines in this locality are both rich and permanent. There are other claims here which would astonish you; should you see them, you would naturally wonder why it is that the mining men of means do not take hold of such property and build reduction works and work them, which can be done with profit.

The Live Yankee and Big Nick, owned by Nick Freyer, contain and now show, with the present development, thousands of tons of ore which would yield a fair profit had he a mill at or near the mines, while Mr. Freyer has ore of a very high grade at or near the surface which is rich enough to ship to Salt Lake. He realized several thousand dollars, and could have realized a great deal more had he reductions works of his own; but he, like a thoroughbred, expended it all in further developing his property. It is not known in the history of mining that there ever was a mine worked which would pay a profit or even the expenses of working, if its owners had to depend upon shipping the ore hundreds of miles to have it reduced.

The Victor Mine.

Owned by Cox & Matile, is the first south extension of the Paradise Valley mine, and, as far as the owners have been able with their limited means to develop it, it proves to be as good as the Paradise itself, which is now and has been paying a dividend monthly for several months past. The Victor is open to a depth of about 80 or 100 feet and shows a ledge from two and a half to three feet in width, and I venture to say that the whole vein would mill \$40 per ton—some of the ore assaying high up in the hundreds—but what can a man do with ore of that kind without a mill of his own? Nothing of course; but the poor owners must toil on some times working for wages in order to procure means to further develop their property, and awaiting for some one who has means to purchase their mines at a reasonable figure.

The Julia.

Owned by Messrs. Carrol, Patterson & Heatherton, is a very fine prospect. These gentlemen have just begun to open their mine with a force of only two men and it is a very common thing to see assays from it as high as \$800; but as a matter of fact, they have not encountered any great body of such ore, or they would be able to realize well by shipping it abroad. These are the only claims on which there is any work being done, except the Paradise company, and why it is that mining men of means do not take hold of such property is a mystery.

ANOTHER ORE CONCENTRATOR.—The Amador *Ledger* gives the following description of a new concentrator which has been invented by Judge Theron Reed of Jackson. The machine has been attached to the one stamp mill of the St. Julian, at Middle Bar, and practically tested with results so satisfactory as to leave no room to doubt its success. It consists of an endless revolving belt similar to the Frue, the belt being made of canvas. Instead of a flat surface, the belt is concave, the depression being two or three inches near the centre. The motion resembles that of a miner's pan in panning out—the most effective motion for settling gold or sulphurets. On reaching the point of greatest depression the sulphurets are concentrated at the bottom, the water and sand are discharged at the side, whilst the slowly revolving belt draws the sulphurets over the other end, where they fall of their own weight or are washed off in passing through water underneath. Attached to the machine is what is called a cut-off. This is simply a sluice-box provided with a shake like the belt. The discharge from the battery first passes through this box. At the end is a slot, the opening being sufficient to admit only from one-half to two-thirds of the pulp. By the time the pulp reaches this slot the sulphurets are at the bottom, and pass through the opening to the concentrator proper; whilst a large proportion of the lighter stuff passes over, and is finally disposed of. In this way the bulk to be treated by the concentrator is very materially reduced at the outset. Mr. Reed has spent five months in bringing the invention to its present stage of perfection. He has applied for a caveat which will give him one year in which to make improvements. The distinct features are the cut-off, the pan-like motion, the concave shape, and the side discharge. It is simple yet durable, and constructed almost exclusively of wood.

Advance in Powder.

The various acid works companies of the city and the various powder companies engaged in the manufacture of dynamite and nitro glycerine descriptions, have been trying to unite on some basis satisfactory to all for sometime. A verbal understanding was arrived at sometime ago. Since then the necessary papers have been prepared, and each interest has signed the agreement. The last signature was obtained from the Vigorit Company at noon, to-day. The parties to the contract include six acid works, embracing the Golden Gate and Western Mineral, and the following Powder Companies: Giant, California, (Hercules), Safety Nitro, Vulcan and Vigorit. The contract is for three years and is of ironclad construction. The basis first fixes on the cost of production, and the difference between uniform figures agreed upon and the selling price is to be turned into a common pool and divided up pro rata. The uniform selling prices agreed upon are about 25c for No. 2 and about 37½c for No. 1. These figures are nearly 50 per cent above the average prices at which these descriptions have been selling for of late in this market. The combination will of course place the companies in a better position than they have been for sometime. Something of the kind appeared to be absolutely needed to prevent an illustration of the Darwinian theory of the survival of the fittest. It is said that Eastern powder companies long ago resolved to similar measures. The Atlantic Dynamite, owned here, makes no powder here, does not import any, and is not a party to the contract. The Giant paid monthly dividends of 75c per share up to last March, when it dropped to 40c. It is thought the 75c rate will be restored next month. The California pays \$1 and will probably make no change. The Safety Nitro has never paid, but under the present arrangement expects to pay 25c per share next October. The Vulcan suspended dividends a long time ago, and has since levied two or more assessments. The Vigorit is paying 10c, and may increase to 15c, though it will cease manufacturing for the present, but will share in the common pool. Its present supply of materials will be sold for account of stockholders. *S. P. Bulletin, June 12th.*

BUTTE COPPER PRODUCT. A New York correspondent of the Butte (Montana) *Inter Mountain* says: There is still a bad feeling in consequence of the recent failures here and the crash; people finally begin to think that there were existing and still exist, just as many rotten concerns in the banking business and stocks, as there were wildcat mining schemes. Investors may more easily be induced to buy good mining properties where they can see something and control the same, and get for their heavy outlay of money fair returns, instead of investing in railroad shares subject to a game worse than poker, and in the hands of trustees using up other people's money for their fool gambling. The copper consumption in Europe was so far in excess of the imports from this and other countries, that a very large reduction in copper prices ought not to be feared any more. Chili bars may yet decline three or five points, but without causing any panic in Europe. It is not likely that below £50 for Chili will be touched. At the present freight rates from Butte, copper mining will pay even at such as £50 for Chili. All that smelters in Butte need is cheaper fuel. Wages for miners are not too high, though outside labor should be lower. There is no comparison between outside labor and miners' labor; the latter is dangerous, risk of life is incurred, and one dollar difference per day should be the least discrimination.

LOVELOCK NOTES.—A correspondent of the *Silver State* says: Last Monday G. W. Bothwell came in from Bernice. He informs us that he has leased the quartz mill to Messrs. Williams & Wallace, who are the principal mine owners of that place, for the period of one year. Those gentlemen will commence crushing ore about the 1st of July. This arrangement virtually settles all disputes between the mill and mine owners of that district, and puts the management of the mill affairs into the hands of the latter. This consummation of the unsettled matters of the past is hailed with a feeling of satisfaction by all concerned in the prosperity of the camp. George Lovelock received an advance of \$1,200 from San Francisco parties on the 15 tons of cobalt and nickel ores he shipped to that place, which is estimated to be but one-third of its value. The ore has been re-shipped to Swansea, Wales, to be worked, and as soon as full returns are given, regular shipments will be made. Mr. Lovelock has a six-foot vein of the same kind.

CLOUDBURSTS in the Humboldt range of mountains have deluged the valley for miles. The Central Pacific has been delayed several hours, the track being washed out in several places between Mills City and Lovelock's, Nev.

GENERAL ORDERS have been issued from the Adjutant-General's office at Sacramento, directing the brigade commander of the N. G. C. to provide for a parade of the State troops on the anniversary of the national independence.

MAJ. BRISBANE, in command of a detachment of troops marching from Montana to Idaho, crossed the main range of the Rockies the 3d of June, and reports the snow several feet deep and the weather still very cold.

USEFUL INFORMATION.

Artificial Glue.

The *Industrial Gazette*, of St. Louis, has seen and carefully examined a small parcel of what is called "artificial glue." The editor says in regard to it:

We have taken some pains to obtain from reliable sources the *modus operandi* of its manufacture. Upon the strength of what we learned, together with a knowledge of its constituents, we made a sample, and it looks and acts precisely like the original. We hope to have some more of the latter in a short time, and will compare the adhesive and other properties, which, if satisfactory to us, we will then compare with ordinary glue and give the results in these columns.

The process consists of dissolving calcic chloride in twice its weight of hot water; the solution is allowed to settle. The clear liquor has a gravity of 30 to 32 B. A mixture is then prepared of caustic potash and soda, 29 to 30° K.—equal quantities of each; a little resin added, and the whole is brought to a boil. The quantity depends upon the degree of consistency required or desired. A mixture of 60 parts solution of prepared tartar - 6 per cent; 127.5 parts H₂SO₄—sulphuric acid (10 B.); 10.5 parts sulphate of alumina (9 B.) is prepared, which will show about 8 B. Then 50 kilos of the calcic chloride solution is placed in a vessel, adding, while constantly stirring, 25 kilos potato starch, previously mixed with 25 kilos distilled water. Then 5 kilos of the above alkaline solution are added and the mass heated, until the mixture has a temperature of 167.5 Fahr.; subsequently, 4 kilos prepared tartar dissolved in 40 kilos of water; 1 kilo of chloride of zinc in 10 kilos of water, and finally, 200 grammes phenolic acid, with 30 grammes nitrobenzene, dissolved in 4 kilos of hot water, are mixed in, stirring constantly.

If the mixture is intended for vegetable fiber or dressing purposes, the resin is omitted. For dressing soft goods less soda than potash is taken.

It has been said that all the products of the cow—her milk, butter, cheese, bones, horns, hide, meat, etc.—have been counterfeited, but that nothing has been found that will pass muster for glue. Now that this new substance is being manufactured and introduced, the old brute cow must give up her glue. Although this glue was originally intended for a bleaching glue, still it is being recommended for joining wood and other substances for which glue is used, but, as before stated, we have grave doubts regarding its efficacy for wood manufacturing purposes. To our positive knowledge, however, the compound is being purchased by an extensive glue manufacturer. As he makes glue to sell, he cannot need it for his own use. Hence there is a possibility that some small portion of a lately purchased car-load may find its way to the packages containing animal glue and nothing else. We have been investigating the substance for some time, and shall continue giving reports of this and other tests as results are reached.

Something New in Photography.

A gentleman recently arrived in New York from London is reported to have brought over some samples of a new and exceedingly curious process of photographing upon marble, by which the picture is made to penetrate the solid block and appear upon the reverse side as well. It is not only on the marble, but in the marble and through it, and cannot be eliminated from it. You may grind on it all day with pumice stone, and you cannot hurt it. So long as even a shaving is left the portrait remains unharmed. Split it up with a saw, and every slice is two portraits.

The gentleman in describing the new process says: "There are secrets connected with it that I could not pry into, but I saw the greater part of the work done in making this picture. The portrait is painted on one side of the marble, whether in oil or not I do not know. When dry, the slab is placed flat on a little car and rolled into an air tight oven of moderate temperature. Under the ear is an open tray full of water, which is heated slowly by gas. After being subjected for some time to a slow steaming process, the slab is suddenly transferred to another oven with a temperature of 300 degrees and kept there till the process is completed, when removed the colors are found to have penetrated the marble, and the picture appears on the other side. I have seen billiard balls subjected to the same process, hundreds of them at a time and beautifully colored. One of them sawed in half showed the same color all through. Handsome chess and checker boards are made in the same way. In fact, a great variety of beautiful and durable work may be done. Wood may be similarly treated. Some will probably be sent to this country at an early day."

TO COLOR SOLDIER YELLOW.—According to a French journal, the soldered places can be colored yellow by wetting them with a strong solution of vitriol of copper in water, and then touching the wet places with the end of an iron or steel wire. Another process to color yellow the soldered parts is to wet it with a liquid composed of one part solution of vitriol of zinc and two parts solution of vitriol of copper, the

place being subsequently rubbed with a piece of zinc, which will cause it to assume a copper-colored appearance, which will take a fine polish. Gold-plated articles thus soldered can be plated again, when the soldering cannot be detected, or the soldered part can be wet with gum arabic water, and when dry polished with bronze powder. Silver-plated articles are to be polished with silver powder.

THE LATEST INVENTION, in the way of office furniture is a stamp with a clock attachment, the hour hand of which is simply a raised point upon a moving circle. The minute hand is an arrow on another revolving circle. An inked tape passes over these indicators and the outer circle of the hour figures. Beside the clock face is a cylinder with several faces, each bearing a word, such as "approved," "wired," "delivered," "answered," etc. Thus when a business man sends a letter, telegram, or receives an order, or transacts any business, he can by the use of this stamp record the precise moment at which the thing was done.

WHITE CLAY FOR BOILER LAGGING.—A correspondent of the *American Machinist* says that the white clay or kaolin found in many parts of the South is used for boiler lagging with excellent results. He says: "I have seen locomotives covered with it placed in the house at 10 P. M., with 130 pounds of steam, and without fire, which showed 60 pounds of steam the next day at noon." The clay is mixed half and half with plaster of paris with jute to hold it in place.

GLASS BRIDGES.—It is said that glass is gradually beginning to take the place of wood and iron in the construction of bridges in England. The inventor makes blocks of glass which he hardens by a special process. In solidity it is said to leave nothing to be desired. The experiments already made have given surprising results, and the cost is below that of bridges of wood or iron. Moreover the glass cannot be injured by insects like wood, nor rusted like iron.

TO PREVENT HAY STACKS FROM FIRING scatter a few handfuls of common salt between each layer. The salt, by absorbing the humidity of the hay, not only prevents its fermentation and consequent heating, but it also adds a salty taste to this forage which all cattle like; besides, it stimulates the appetite and assists their digestion, and so preserves them from any diseases.

GOOD MEALTH.

Eating at Night.

Popularly eating at night is thought injurious, but unless dinner or supper have been late, or the stomach disordered, it is harmless and beneficial—i. e., if one be hungry. Four or five hours having elapsed since the last meal, invalids and the delicate should always eat at bedtime. This seems heretical, but it is not. Food of simple kind will induce sleep. Animals after eating instinctively sleep. Human beings become drowsy after a full meal. Why? Because blood is solicited toward the stomach to supply the juices needed in digestion. Hence the brain receives less blood than during fasting, becomes pale, and the powers become dormant. Sleep therefore ensues. This is physiological. The sinking sensation in sleeplessness is a call for food. Wakefulness often is merely a symptom of hunger. Gratify the desire and you fall asleep.

The writer recently was called at two a. m. to a lady who assured him that she was dying. The body was warm, the heart doing honest work. To her indignation he ordered buttered bread (hot milk or tea were better) to be eaten at once. Obeying, the moribund lady was soon surprised by a return of life and desire to sleep. The feeble will be stronger at dawn if they eat on going to bed. Fourteen hours lie between supper and breakfast. By that time the fuel of the body has become expended. Consequently the morning toilet fatigues many. Let such eat at bedtime and take a glass of warm milk or beef tea before rising. Increased vigor will result. "But the stomach must rest." True. Yet when hungry we should eat. Does the infant stomach rest as long as the adult's? The latter eats less often merely because his food requires more time for digestion. Seldom can one remain awake until half-past ten or eleven in the evening without hunger. Satisfy it and sleep will be sound. During the night give wakeful children food. Sleep will follow. The sick should invariably eat during the night. This is imperative. All night the delicate and children may take warm milk, beef-tea or oatmeal gruel. Vigorous adults may also eat bread and milk, cold beef, mutton, chicken and bread, raw oysters, all of course in moderation. Do not eat if not hungry. Eat if you are.—*Boston Physician.*

FRESH PAINT.—The current belief among householders, the smell of fresh lead paint is noxious, is founded on pretty general experience but is supposed by the opinion equally current among chemists, that lead compounds are not volatile. A fact recently brought to the notice of our excellent contemporary, the *Lancet*, supports the domestic theory. The basis of the useful and

popular luminous paint is known to be sulphide of calcium. Now, this compound, when unprotected by varnish, glass, or some other impervious substance, is slowly acted on by the acids of the air, and sulphureted hydrogen is evolved, which blackens lead paint. This is well known, and can easily be avoided by proper protection of the paint. But the curious thing is that unprotected luminous paint is found to be perceptibly blackened by the fumes from fresh lead paint. There seems to be only one possible explanation of this; namely, that a surface freshly covered with lead paint does actually emit some volatile compound of lead. We believe that many physicians could confirm this view from their own observations in regard to newly painted houses.

TELEPHONES AND IMPROVED HEARING.—It appears, says the *New Haven Register*, that many people who have telephones in their houses or places of business, and use them frequently, find their hearing bettered. The best testimony, however, comes from the central office: At each switch-board sits an operator, generally a girl, who, from morning till night haggles with unreasonable subscribers till her head fairly rings with "hello," "all right," "go ahead." Now her ear is drilled to catch the faintest sound. If an operator were to take a switch-board one day in the week, only, and do all the work required on that day the practice would doubtless be detrimental, because it would be exhaustive to both the muscular and nervous make-up of the ear. Systematic use of the telephone seems to develop the hearing above its normal acuteness. The difficulty which people find in working the telephone comes from inability to fix the attention on what is heard.

GREAT STRENGTH OF THE ANCIENTS.—Physical superiority of the ante-Alexandrian Greeks to the hardiest and most robust nations of modern times, is perhaps best illustrated by the military statistics of Xenophon. According to the author of the "Anabasis," the complete accoutrements of the Spartan soldier, in what we would call heavy marching order, weighed seventy-five pounds, exclusive of the camp, mining, and bridge-building tools, and the rations of bread and dried fruit which were issued in weekly instalments and increased the burden of the infantry soldier to ninety, ninety-five, or even to a fully hundred pounds. This load was often carried at the rate of four miles an hour for twelve hours per diem, day after day; and only in the burning deserts of southern Syria the commander of the Grecian auxiliaries thought it prudent to shorten the usual length of a day's march.

LINIMENT FOR RHEUMATISM.—A patented, and what is said to be a most excellent liniment for inflammatory rheumatism is given as follows:—The proportions being known only to the patentee: Alcohol, pure cider vinegar, kerosene oil, spirits of turpentine, ground Cayenne pepper, ground French mustard, flowers of sulphur, ground ginger and carbolic acid. These ingredients are mixed cold and thoroughly mixed by agitation and stand twenty-four hours, when it is ready for use. In use the composition is applied externally to the part of the person affected, and the operation repeated every few hours. The same liniment is also pronounced good for sprains, bruises, weakness in the back or side, etc.

CONCENTRATED OXYGEN.—The curious statement is made by a writer in the London daily *News*, who has been collecting some particulars regarding diving operations on the Thames and elsewhere, that men have grown old in this particular business; though in early life they had been in danger of consumption. The theory is a simple one. Men under water in a diving dress breathe a condensed atmosphere, and are therefore inhaling oxygen in a concentrated form; and this, it is assumed, is conducive to the cure of consumption.

PALPITATION OF THE HEART.—A French physician says that distressing or excessive palpitation of the heart can always be arrested by bending the body double, the head down and the arms hanging, so as to produce a temporary congestion of the upper portion of the body. In nearly every instance of nervous palpitation the heart resumes its natural function. If the movements of respirations are arrested during this action, the effect is still more sure and rapid.

POISONOUS COLORING IN COFFEE.—It appears from the recent investigations of the New York City Board of Health that both arsenic and lead have been found in raw coffee, which had been put through some process to improve its color. Other deleterious substances are also used in coloring coffee. Their use was promptly stopped by order of the Board.

TREATMENT OF EARACHE.—It is said by the *Medical Record* that by following the simple method here given almost instant relief of earache is afforded: Put five drops of chloroform on a little cotton in the bowl of a clay pipe, then blow the vapor through the stem into the aching ear.

OIL OF WINTERGREEN mixed with an equal quantity of olive oil is recommended as a rheumatic painkiller.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA

Amador.

TUNNEL.—Amador Ledger, June 14: The contract for the first 1,000 ft of the big tunnel at Middle Bar was finished last week. The work is at present being prosecuted by day labor. The header is in slate. Bids are called for sinking the Mahoney shaft 100 ft deeper. It is gratifying to be able to state that good ore has been struck in the new shaft of the Lincoln mine, which has been leased by S. D. R. Stewart. How large the ore body is we have not heard, but from the fact that 20 stamps of the Lincoln mill are being put in readiness to commence crushing, we should judge that it is of considerable size. No man in Sutter creek deserves success more than Mr. Stewart, for no one has been more enterprising and persistent in the development of the mineral resources of that neighborhood than he.

Calaveras.

MILL.—The work of erecting a 10-stamp mill on the Marshall mine is being rapidly prosecuted. Mr. J. Rider, of this town, one of the best mill-wrights in the State, is employed to superintend the work. The Marshall is a rich mine, and when the mill gets to work, we may look for big returns.

El Dorado.

GRIZZLY FLAT MINES.—*Republican*, June 12: A recent visit to Grizzly Flat and some inspection of the mines in the vicinity has convinced us that no better opportunity for the investment of capital in the mining industries can be found on this coast. There is an abundance of gold-bearing quartz, and excellent natural facilities for working it. The whole of this mining district is overgrown by pine and oak, and the swift streams of the Middle and North Fork of the Cosumnes river can be made to furnish water-power. Many of these rich ledges are small and variable at the surface, and this fact has to some extent discouraged prospectors. Considerable prospecting has been done from an early day, but the work has usually been done in a desultory way by men of limited means, unable to prosecute the search to any considerable depth. Scarcely a mine in the whole district, save the Mt. Pleasant, has had a fair opportunity to demonstrate either its worth or its worthlessness. The district needs capitalists who are able to sink 500 ft on these ledges without pausing ten years at a time to take breath. The history of the Mt. Pleasant mine indicates what may be done by men of wealth and energy. The formation of this mine at the surface was not more flattering than that now possessed by other mines in the same locality. It was worked in a desultory manner for years without being considered, and finally sold to the present owners, who, by the management of Capt. Smith, the Supt., have developed it into one of the best little mines on the coast. The shaft has reached a depth of 630 ft and below the 500 level there is a body of paying ore that reaches a width of seven ft and that will furnish profitable work for at least two years without going any deeper. The very appearance of the mill indicates prosperity. Everything is built permanently and during the last 15 months the company has introduced eight Frue Concentrators to be used in saving the sulphurets that form a valuable part of the ore.

INDIAN DIGGINGS.—*Cor. Amador Ledger*: The Edger mines at Mendon are the best paying mines in this neighborhood at present. They are worked by means of drift and hydraulic power. The Baughman and Hale mine at Indian Diggings is being worked day and night. The Spring gulch mine, situated half a mile north from Indian Diggings, owned by Chas. Estey, G. S. Estey and W. McClary of Olea, is being opened up by means of a hydroc tunnel. Gravel has just been struck which prospects well, and the main channel will soon be reached, when it is expected to be one of the best paying gravel mines in this vicinity. The Ball mine has ceased to pay as it once did, but the brothers are prospecting in the vicinity. The Crystal quartz mine near Mendon or Brownville is said to be paying handsomely. These are the only mines worthy of mention in this locality, all of which do not employ over 40 hands. For the benefit of Amador prospectors who occasionally wander into this locality on a prospecting tour, I will say that there is now but little chance for finding good mines, for nearly all the ground is located. I do not wish to discourage the army of prospectors who might venture into our camp, nor do I wish to encourage it when I know that this part offers no encouragement to that kind of immigration. Indian Diggings is situated on the south side of a large mountain range, and commands a sublime view of the far-reaching mountains and forests; has a good climate, with excellent water. One of my contemporaries, in writing to the *El Dorado Democrat*, says this is one of the most favorable places in the country for prospecting; that the mines are all paying; and that there are hundreds of acres of good favorable ground open to prospectors. To all such reports I would say give no heed. Men of money and means come upon the strength of such reports and go away disgusted and discouraged. The sulphurets are hauled to refining works in Amador county at an expense for freight that must give an idea of their richness. The mill has twenty stamps, and it seems strangely out of place among the tall pines that grow closely about it. The Melton mine, now under the management of H. H. McClellan, promises to equal the Mt. Pleasant in the near future. It is on the south side of the North Fork of the Cosumnes, two miles north of Grizzly Flat. The ledge extends approximately north and south, and varies in width from two to four ft. A 15-stamp mill has been built on the edge of the river where the ledge crosses, and water power is furnished by a ditch two miles long, which takes free water from the stream. About a half-mile south of the mill a shaft has been sunk 186 ft, from which paying ore is now being hauled to the mill. The works that promise the greatest returns, however, are on the steep hillside south of the river and the mill. This hill has an altitude of about 500 ft, and on the face of it are four tunnels tapping the quartz at various depths. The ledge is similar to the Mt. Pleasant, and improves as depth is reached. All the necessary preparations for handling the quartz and conveying it to the mill are completed, and the

abundant wood and water power added to facilities for extracting the ore and draining the mine through tunnels, insure unusual economy in milling. An air compressor has just been purchased, and in a few weeks a National drill will be set to work in the fourth tunnel, and another in the new tunnel from the mill as soon as a face of solid rock is obtained. At the time of our visit five stamps in the mill were crushing twenty tons of rock from a mine partially owned by A. A. Gignac. Favorable returns were indicated.

GRAND VICTORY.—*Mountain Democrat*, June 11: This mine, located near Diamond springs, has always produced low grade ore, but under the management of Supt. C. A. D. Gray with a mill of fifty stamps, it has been made to pay. Mr. Gray is not the man to operate a mine for fun, and the report got out some two weeks ago that the receipts did not cover the expenses, when it was said on our streets that work would be suspended. We are assured this is a mistake. Forty stamps are kept hammering away, and the plates indicate a better quality of ore than has been crushed for months.

NEW MILL.—The owners of the Alhambra mine, Kelsey township, from which over \$20,000 has been taken out, the mill in use being a mortar, have determined to erect a mill at once and proceed to thoroughly develop the property. R. H. Redd will continue to direct the work, while Ballard and Weatherax will look on and hope, as every miner who has examined believes that the deeper they go the better it will pay.

Mono.

STARTING UP.—*Homer Index*, June 16: The Gorilla will start up full handed to-day. The tramway has been cleared of snow, put in thorough repair and a new cable added to the upper section. The company's reduction works are still running on ore left over when work was suspended last winter, a goodly quantity of which is still on hand. The new Planet mill arrived on Tuesday last, and is being put in position at the reduction works. The May Lundy is now running full handed, the tramway, teams and mill having been started up on Thursday. Work will not be commenced on the Lake View till the additional five stamps are in position. The Bryant mine is yielding some very fine ore from the 130 level, and arrangements are being made to get the ore down to the Butterfield mill. Reports from the Great Sierra tunnel in Tioga district continue very favorable. The rock is still soft, and is filled with seams of quartz.

BODIE.—*Free Press*, June 16: The Standard is still running 15 stamps in the Standard-Bulwer mill, and is expected to clean up at least \$8,000 to-day. This is certainly a good showing for the number of stamps employed during the past week. Two sets of sluice are now in operation below the Bodie tunnel mill, one of which will do remarkably well according to tests made.

BODIE CON.—During the past week there was 546 tons of ore crushed at the mills. The average assay value of the pulp is \$22, and of the tailings \$2. The pulp assay is no test of the value of the ore. The only way to get at the value of the ore is at the weekly cleanup. See the number of tons crushed and the amount of bullion shipped; this is the true test of the value of the ore. North drift from upraise No. 4 is in 67 ft. South drift from upraise No. 1 is in 26 ft. North drift from winze No. 2, 306 level, is in 38 ft. There is no change in the ore-breasts since last report.

STANDARD CON.—Since resuming operations we have extracted and shipped to the mill 654 tons of ore; received 720 ounces of crude bullion, and shipped to the company this day \$5,845 74. South drift No. 4 from east crosscut No. 2 has been extended during the week 10 ft, and is now in 146 ft. The vein in the face is 2 ft wide.

BULWER CON.—The south drift from west crosscut No. 2, 500 level, is in 284 ft; progress during the week 11 ft. Vein about 15 inches wide.

BODIE TUNNEL.—The north drift on the vein, 200 level, was advanced 20 ft. The vein in the face is improving, while the rock breaks about the same.

Plumas.

GREEN MOUNTAIN.—*Bulletin*, June 11: Fine progress is being made in the main raise in the Blake chimney. It is now nearly 400 ft from the No. 6 tunnel, and is advancing at the rate of about 35 ft per week. With no unforeseen delay, connection will doubtless be made with the No. 5 level in about ten days. Raise No. 2 is 68 ft east of the main raise and is now about 125 ft up, and is in good quartz. The Blake chimney is being opened by three blind drifts which are respectively 84, 181 and 285 ft from the No. 6 tunnel. Connection has been made in No. 1 blind drift east with No. 2 raise and stope are being started and ore chutes put in at this point. Work has been discontinued on No. 6 tunnel west, on account of air, but as soon as the raise is through to No. 5 level, the drills will be started again and work prosecuted vigorously until the sulphuret chimney is reached, a distance of nearly 300 ft from the present face. At present the Co. are running only 3 stamps, which are being supplied with ore from the two raises and the blind drifts; but the 60 stamps will all be in operation in two weeks more, and the mine will be in shape for a long and profitable run. The mining outlook for this section of the country is much better than it has been for some time. Few of our ledges in this part of the state have been sunk on to any depth. Hitherto the miners have been digging in the grass roots, so to speak. The work on the Green Mountain mine has demonstrated the correctness of the theory that our ledges improve with depth. That mine is looking better than for years before. There is no reason to doubt that the Crescent mine has thousands treasured in its ledges at no great depth. All that is required to make an excellent property of it is to get it out of the legal entanglements that now hamper it, and expend a little capital wisely in its development. The Sun Set is running smoothly, and the ledge in the drift has widened out and is prospecting well. In the east and west end of the Firststone stope, the ledge maintains a uniform width of four ft, with a decided improvement in the quality of the ore, some parts of the ledge showing free gold. Miller & Leck are hunting for a rich pocket in the "Miller" claim, formerly known as the Pulsifer mine. This claim has yielded well during the spring, two rich pockets having been discovered and worked out. Firststone & McGraw are hauling quartz from their mine on Washington Flat, to the Crescent mill, which has

been leased by them for a short time. A good clean up is expected from a short run.

WILL MAKE A TEST.—*Plumas National*, June 14: We are informed that ten tons of Lucky S. rock will soon be brought from the mine and crushed in the Premium mill, near the Blood Ranch. If the test proves satisfactory the Company will put up a mill on the mine at once, and as the rock prospects well there is very little doubt but that it will prove good.

HALLSTED MINE.—Messrs. James and Hosking returned from the East Branch on Saturday, having made their inspection of the Hallsted mine. Mr. James informed us that the East drift from the tunnel looks very favorably, but the air is so bad that the men could not work in it, and no developments had been made there for several weeks. The West drift is not looking so well, the rock being so hard and gray. The Company only had until the 1st of July to finish their prospecting work, and as it would take some three weeks to make arrangements for a supply of good air, they concluded to stop work. The owners were not disposed to extend the time for prospecting. Mr. James speaks highly of the appearance of the ledge in the East tunnel, and intimates that there are strong probabilities of a permanent and rich mines but did not consider the developments sufficient, as yet, to warrant the purchase by the Company.

San Bernardino.

DAGGETT SAMPLING WORKS.—*Calico Print*, June 14: These works were opened for business on Thursday of last week, and the results of the first week's run, as we learn from L. F. Olmsted, the manager, have been highly satisfactory. Seventy tons of ore have been crushed, sampled and paid for, and more is arriving daily. Mr. Olmsted has paid out nearly \$6,000 already, and is shipping earloads of very desirable ore to the smelters East and West. The first car averaged over 400 ounces silver per ton. The general average sampled is 167 ounces per ton. As far as we can learn our miners are highly pleased with the new mill and its methods of transacting business. Many parties have lately outfitted here to start work on galena and copper mines in this vicinity, that have laid idle for want of a market. Several lots of such ore have been milled with very satisfactory results. Our merchants and business men should awake to the situation, and be prepared to meet the demands of the trade that will center here for 150 miles around. A bank should be started here at once, for a business of \$100,000 monthly requires it. These are solid facts, as solid as the ponderous silver bars that are daily dumped into our Express office.

Sierra.

GOLD BLUFF.—*Mountain Messenger*, June 7: Mr. Van Slyke has seven men employed at the Gold Bluff mine. He has abandoned the upper workings and is running the lower tunnel night and day, doing now in very good working rock. The tunnel is in 500 ft. He has rigged a water-blast in which he takes much pride, as it is his own engineering. One thousand feet further will bring him to the ledge and give him 300 ft backing. He has unbounded faith in the mine. P. A. Jamping came down from Hog Canyon Tuesday, and reported that he had pushed his tunnel through hard blasting formation into soft picking rock, with every indication of being very close to the ledge in the Good Hope claim, supposed to be very rich, where the Primrose obtained such good pay. Snow is four feet deep and melting fast. An extensive slide occurred in the Last Chance claim, at Howland Flat, last week, which came near being a last chance, indeed for several white men and a whole gang of Chinese. Without any warning the bank slid from the pipeclay, catching six men, but they were rescued alive. There were several narrow escapes. A very rich quartz discovery is reported from the neighborhood of Chips Hill, near the root gravel claim. The quartz is said to be rich in silver as well as gold. The twenty additional stamps now being added to No. 9 quartz mill at Sierra City, are expected to be running by the 1st of July. We learn that the root claim on Chips Hill, is getting a good prospect again—better than for a long time past. The gross yield of the Bald Mt. Extension Mine for April is \$5,049 60; Pay Roll, \$4,395 62.

PROGRESS.—*Mountain Messenger*, June 14: The rock in the Red Oak tunnel is not so hard now as it has been, and more rapid progress is being made. The chances are favorable for the tapping of a rich gravel lead at an early day.

NEVADA.

Washoe District.

ALTA.—*Enterprise*, June 14: Good headway is making in the west drift on the 2150 level, though the rock is hard. The diamond drill has not been started east from the face of the east drift on the 2150 level, and will not be until the ground to the westward has been explored. It is very probably that when the water to the eastward is tapped it will require a considerable length of time to drain out. It is known that this east body of water extends upward to the level above, and very likely portions of it reach still higher in breaks and crevices in the rock.

UNION CON.—There is as yet no noteworthy change in the material encountered in the east crosscut No. 4 on the 3100 level. There is a considerable amount of water flowing from the drift, but the quantity is not sufficient to materially interfere with the operations of the workmen. The ground to the eastward of the main north and south drift is also draining off through two or three diamond drill holes.

BEST AND BELCHER.—The east crosscut on the 1200 level is still encountering a considerable amount of quartz. It is being advanced into a very favorable formation. As the drifting is now wholly on the upper levels, the waste rock is being taken out through the old lower tunnel, and no hoisting is being done at the Osbiston shaft. The pumps at said shaft are kept going, however.

COMBINATION SHAFT.—Are cutting out a working station at the 2900 level and also preparing to set up the Cornish pump at this point. The pump will be in place and running in about three weeks. In about the same time the bulkhead in the Chollar on the 2600 level will be completed.

CHOLLAR.—Are preparing to place a stone bulkhead in the drift on the 2600 level, that in the Savage having been completed. This bulkhead will be completed at about the same time that the Cornish

pump will go into operation at the 2900 level on the Combination shaft.

YELLOW JACKET.—The prospecting drifts are still finding ore in addition to that already opened up, therefore the mills are likely to be kept busy during the whole season.

MEXICAN.—The winze started on the 3100 level has been sunk to a point 10 ft below the 3200 level, where a station is now being cut out.

HALE AND NORCROSS.—Are shipping ore to the Mexican mill, on the Carson river. About 700 tons have already accumulated at said mill, where a crushing of 1,000 tons will soon be made.

CON. VIRGINIA.—The east drift on the 2900 level has been advanced about 30 ft. Have completed repairing the C. and C. joint shaft. Have also completed a cooling-off house for the use of the miners working in the heated drift.

ANDES.—A considerable amount of prospecting is being done. A great deal of quartz of a fine appearance is being encountered and some spots of ore that will pay for milling are occasionally met with.

GOULD AND CURRY.—Good headway is making in the two crosscuts that are being run to the east on the 1200 level. The material is a favorable formation, consisting of a mixture of quartz, clay and porphyry.

SIERRA NEVADA.—The north drift on the 3100 level is making good headway in vein material of a favorable character. Thus far very little water has been encountered in the drift.

IMPERIAL.—The lateral drift, now in Alpha ground, is encountering a considerable amount of quartz, but thus far it is not found to carry metal in paying quantities.

BELCHER.—About the usual amount of low grade ore is being extracted on the old upper levels, which is being shipped to mills on the Carson river.

UTAH.—The southeast drift on the 1050 level has been extended 33 ft; total length, 178 ft. It continues in a favorable vein formation.

CROWN POINT.—About the usual amount of low-grade ore is being extracted and sent to the mills on the Carson river.

UNION SHAFT.—Repairs are still being made to the drain drift connecting with the Sutor tunnel on the 1600 level.

OMIR.—Are sorting out fillings in the various drifts on the 250 level.

Bald Mountain District.

PLACER AND OTHER MINES.—*Enterprise Sentinel*, June 12: Judge Adams and Andy Swick came in from Bald Mountain yesterday and report favorably of that district. Not only are there well defined gold quartz veins being developed there, but gravel placers have been traced through the gulch for a distance of three miles, and operations are now being inaugurated in them. Andy Swick, Dick Robinson and two other men started in lately to sluice the gravel, and got down about five ft. They worked for about three hours, and got three dollars. They think that when they get properly fixed for work they can make from five to ten dollars per day to the man, as long as water lasts. They have at present about 60 inches of water running through the gulch, and have come in after lumber and other material to make sluice boxes with. The gold is heavy, bright and in small particles, of the consistency of sand up to the size of a grain of wheat. The pay gravel is in the bottom of the gulch and on part of the hill sides. In no place has a greater depth than five ft been attained. Bedrock has not yet been touched, but the gravel gets richer with depth as far as they have sunk in it. They are now running their sluices, and will increase their facilities for working immediately, so as to take advantage of the water. No washing has ever been done before this season. It is thought that the gold comes from the quartz veins and the Tim Peak ledge. The latter Judge Adams is interested in, and from the description he gives of it it is a peculiar vein. It crops out near the top of the hill at a point about 500 ft above the gulch. It has the appearance of oxidized iron ledge matter, with rounded pebbles all through it, which seem to have washed into the ledge. Where the vein was discovered it is bent over flat, and a ledge of calc spar has forced through it in such a manner that it appears near to the surface as parts of the vein itself. The whole thing is capped over with porphyry, or rock of a nature similar to it. During the course of development it has been ascertained that the spar forms one of the walls of the vein, but whether the hanging or footwall has not yet been determined. It is intended to run a tunnel in on the ledge from the gulch to develop the mine in that way.

Columbus District.

MOUNT DIABLO.—*True Picture*, June 7: The east intermediate from winze No. 5 shows some \$60 ore that looks very encouraging, and the west drift from the same winze shows a narrow streak of good ore. This drift has been advanced 8 ft during the week. Winze No. 6 is now down 111 ft, and work has been stopped on the same. The fourth level is being driven west to connect with this winze. In the intermediate, between the second and third levels and west of the shaft, the west drift is in 46 ft and shows a strong ledge of low grade ore. The raise from the east drift on the first level shows a little ore of fair grade. The incline is now timbered from the fourth level to the chute on the third level, and hoisting will begin from the same in a short time. As there is a great deal of waste to hoist it will take some time before sinking is resumed.

COLUMBUS CON.—Crosscut No. 3 from the main drift on the 150-foot level was extended 5 ft during the week, and is now about 53 ft in length. Near the face of the crosscut a two-foot vein of good ore was encountered that promises well. The average grade of the ore in the streak is \$92, and drifting on the same will be commenced in a few days. The upraise on the ore in the south crosscut from the same level is now up a distance of 30 ft, and is about 15 ft in width at the top. The width of the streak of ore is about the same as last reported, and the grade is \$40 per ton. No work is being done except on this level, but it is expected that general work in the mine will be resumed at an early day.

Cortez District.

VALUABLE MINE.—*Reese River Revue*, June 17: Away back in 1863 Andrew Vetch discovered a mine in Cortez Mining district. Two years later Simon Wenhan bought him out and began to open it out. He had a long and discouraging time of it,

but through years of despondency and poverty he struggled on against obstacles which would have discouraged most men. He was unable to pay his men and as a consequence they quit him and he kept getting others, until finally he had only Chinamen at work. But at last success crowned his efforts, and the mine began to pay. Since then he has quietly been taking out the silver by hundreds of pounds. All his debts are paid and he is reputed to have a few dollars between him and the poorhouse. The Cortez mine is worked by a tunnel which is run into a high hill about half way up the side. The ledge is a big one, and the ore free milling. He can take it out faster than the mill now in use can work it, and is about to build a new 10-stamp mill this summer to help reduce the ore. The bricks are already being burned for it. The mine is as dry as a powder horn. In fact they have to haul all the water used at the mill and houses in wagons a distance of two miles up the hill. Originally they had to carry it six miles, but pipes have been laid to bring it within two miles. Sixty men are employed underground, and about forty on the surface. Mr. Wenban has his mine patented, so his title is perfect. The mine itself is in Eureka county, while the boarding-house and store are in Lander. It is likely that the Cortez mine is one of the best now being worked in Nevada, and Mr. Wenban is very quietly minding his own business and getting rich.

Comet District.

FAVORABLE PROSPECTS.—*Pioche Record*, June 7: Judge Clapp took a trip out to comet district during the week. He speaks very favorably of the prospects there. He states that the claim owned by Freudenthal & Co. is a very promising one.

Eureka District.

NOTES.—*Eureka Sentinel*, June 14: The Liberty mine, in New York canyon, is being worked under lease, with good prospects ahead. The Silver Connor mine keeps up its reputation, and sends from 10 to 12 tons of ore to the Richmond daily. H. K. Mitchell, one of our most indefatigable mining men, is developing some good mines in Secret canyon. The amount of custom ore being sent to the Richmond furnaces greatly exceeds that of any previous season. The bins and platforms are full, and piles of ore are distributed all over the yard. Jim Coates has located a placer claim at Bald mountain, just below that of Andy Swick & Co. He started to work last week with John Fryer, and sunk two ft in the ground. The result was good, as five cents to the pan was obtained. Jim thinks that if he can get all of such quality of pay dirt as he can shovel into the sluices it will be all that he will want to make him rich. He has come to Eureka to purchase lumber to make sluice boxes, and on his return to Bald mountain will make things hum.

Daily shipments of ore are being made by tributaries from the Hamburg mine, Peelslick hill. Martin Planton has a large quantity of ore broken down in the Dead Broke mine, but has not yet determined to what furnace he will ship for reduction. A fine prospect has been struck in the south drift, 200 level, of the Eureka tunnel. The ore is quartzite, and is much like the ore of the Addison chambers in appearance. The machinery at the Connolly mine is in fine running order. The mine looks well, and a change, still for the better, has taken place in the contractor's drift. The face is in open ground with red line on one side of the fissure. H. B. McKee has two men employed prospecting the Endeavor mine in Page canyon. They are running a drift from the north shaft to cut an east and west fissure. It is now within 20 ft of completion, and the prospects for finding ore are good.

Pinto District.

HIGH GRADE ORE.—*Eureka Sentinel*, June 14: Andrew Berryman, Tom Mellon and Richard Berryman have shipped 10 to 12 tons of high grade ore to the furnaces from Silver Nugget mine, Pinto district, during the week. They have a large quantity of low grade ore broken down, which they will hold in reserve for better terms than can be had at present. The mine is looking exceedingly well, and they have reasonable expectations of encountering large bodies of ore during the summer. John Steel is doing good work in the Diagonal mine, Maryland mountain. He has some high grade ore on the dump and is breaking more of it down.

Secret Canyon District.

PROSPECTING.—*Eureka Sentinel*, June 14: Jim Murray, with two tributaries, is prospecting the Alliance mine. A drift is being run on a quartz seam about 30 ft from the surface. The Scorpion is being worked by three men on tribute. They are at present running on a bunch of good quartz that may open out into a bonanza. Some prospecting work is also being done with chances for success in other parts of the mine.

ARIZONA.

TURKEY CREEK DISTRICT.—*Cor. Prescott Courier*, June 12: Mining is looking up in this stanch old district. The miners are all hard at work delving in the mines, or assorting and sacking ore for shipment. The old district keeps jogging on in a busy way, with an outlook brighter than a silver dollar. Most of the machinery for the Chase Co. has arrived, and the company is pushing work vigorously. The Wonder mill is going up fast. It will be the most complete gold mill in Northern Arizona, and will drop its stamps on or about the 20th of June. The A. C. M. Co.'s mill, at Buena, is being remodeled, concentrates put in and the works put in fine running order. The company will purchase and work custom ore. Mr. Whiting, late of Tip Top, an efficient mill man of much practical experience, has charge of the works. The company will commence crushing ore in two weeks, and Mr. Whiting is sanguine that he can run the mill to the satisfaction of the chloriders and with profit to the owners. The Franklin Co. has the whim up on the Union shaft, and will commence sinking and drifting immediately. Some of the best ore of the district has been taken out of this mine, so we may look for rich developments as work progresses. Morgan & Co. are assorting and sacking ore from the Pine Spring mine. The mine will start up soon. In turning down the mountain west of the Yankee Boy, McCann struck high grade ore in the Longfellow mine, 140 ft below the surface. McDonald is sinking on the Yankee Boy, and taking out very rich ore. Five tons of ore from this mine is now ready for shipment. McDonald says it will work over \$800 per ton. The Ready Pay is a very

promising prospect—samples from \$90 to \$1,115 per ton. The claim was recently purchased from Mr. Cotten. Mr. Mulvenon is sinking on the June Bug, which is a strong vein. The ore is very rich in horn silver. Mulvenon & Roach are also drifting on the Roach mine. This mine looks as well as any in the district. Keating & Co. are drifting on the Holmes (75-foot level); drifts show a fine body of ore. Kowell is sinking on the Syndicate. He is taking out very rich chloride ore and will soon make a big shipment. Mr. Howard is sinking on his claim, situated below the Brick Yard. The ore is good, and the prospect for a big mine is very promising.

BONANZA MINES.—*Quijota Prospector*: The developments during the past week have proved beyond a doubt that the ore body extends, at least, to a depth of 200 to 300 ft from the surface of the hill. The company will probably decide, very shortly, whether they will build a mill at once, or wait until connection has been made from above with the tunnels. Should the latter course be decided on, it will be several months yet ere reduction works are erected. What has been done so far, has been merely prospecting work, yet about 50 men have been employed steadily, involving an expenditure of from \$6,000 to \$7,000 monthly. Had and eastern company purchased these mines, one-tenth of that work would probably have been the result. There is sufficient ore in sight now to run a 20-stamp mill for several years, but the bonanza company are not in the habit of putting up mills until they can do so on a large scale, and have enough ore actually in sight to run them permanently. Had other companies pursued this course in the territory, Arizona would not have received so many serious setbacks in the past ten years.

MOHAVE.—*Miner*, June 14: Messrs. Roe, Elliott and Luthy, who lately leased the Paymaster mine, have already put the main shaft in order, and put in a platform above the water level. They have now a force of eight men at work stoping and drifting in the upper levels under the foremanship of Henry Elfers. The force will probably be increased very shortly. We need two or three smelters like the one at Denison in this county. Austin and five other men are grading a road up to the timber in the charcoal canon near Cerbat, for the purpose of supplying the mill with wood. The new smelter at Planet is in running order, and already ten tons of bullion have been turned out. There are over fifty men employed in and around the smelter. W. H. Hardy has eight men at work on the Infalible mine at Stockton. The new tunnel which he started a short while since is in about 120 ft, and is being driven at the rate of six to eight ft per day. Richard Hicks and James Oliver, two Cornish miners and recent acquisitions to this district, have leased the Pennsylvania mine in Todd Basin of Capt. Layne for one year, and will at once start to work on it. They have also bonded the mine for the same time for the sum of \$15,000.

THE CERBAT MILL.—Six men have been at work on the Cerbat mill for over two weeks past, putting it in perfect order. The mill started up on Thursday with about 150 tons of ore to commence on. Among the shipments already contracted for by this mill we note twenty tons from the C. O. D. mine, besides several smaller lots from the mines in the same basin, five tons of ore from Joe Labaree's claim near Stockton, with considerable second grade ore, fifteen or twenty tons from the Prosperity mine in Todd Basin, owned by Caldwell Wright and J. P. Layne, while Wm. Sherman sends a couple of tons from the southern extension of the same mine as a sample. In addition to this there are about 30 tons of ore from the Cerbat mine already at the mill, and about 50 tons at the Paymaster ready to be hauled down. Many other miners have promised to send in shipments of ore, and by next week Cerbat will present quite a lively appearance.

PECK.—*Prescott Courier*, June 14: Mr. Rowe returned home recently from Peck and other mining districts. From him we learn the following: The Buzzard and Raven mine, near the Dosoris, has 18 inches of rich galena ore, which will pay for shipment to Pueblo or any other place. McDonald has another lot of ore out of the Mark Twain mine. He ships through First National Bank, of Prescott. Dave Grubb has a great deal of rich ore at his mines on Hassayampa creek. Mr. Caigne, Supt. of the Dosoris, has, in the past month, shipped 103 tons and has about 75 tons more ready for shipment. The First National Bank ships this ore to Pueblo, Colorado. Frank Alters and co-owners of the Coschoot mine, near Copper Basin, has plenty of shipping ore, and think of sending more of it to Pueblo. A former shipment made by them paid well. Negotiations are still pending for starting Lynx creek reduction works. United Verde Co. have enough coke on hand to run their smelter a month.

THE LYNX CREEK PLACERS.—The Eastern parties having a bond on this property failing to come to time, Governor Trile, in company with the Murphy Bros., it is rumored, will hereafter operate these rich diggings. During the last winter, it is said that nearly \$20,000 in gold was taken out by the Lynx Creek Hydraulic works—the last installment of which, \$2,600, is on deposit at the Bank of Arizona. Parties in a position to know, estimate that during the last sixteen years, over \$500,000 in fine gold has been taken from this creek, in the vicinity of Prescott.

COLORADO.

SOLID EMPIRE.—*Colorado Miner*, June 14: During the past two months the *Miner* has expressed unbounded confidence in the Empire mines. For some years the old gold camp has remained idle with but few mines worked, and but small production. Yet within the camp lie still undeveloped mines, worth millions when once brought into the market as active producers. A few weeks since the *Miner* reported the purchase of property by a wealthy German company, that will during the year develop their property by thousands of feet of shafts and tunnels. They are preparing for deep mining, and will prosecute the work with vigor. Later was reported the sale for \$30,000 of the Pittsburg group, which has shown well in the past and paid largely. Yesterday we received the news of another, and the largest sale made for years in this camp. It is a bona fide sale, and the property has been transferred. Colonel John M. Dumont purchased of George G. Vivian, Samuel J. Vivian, and Herbert S. Vivian the Neath mine. The price paid was \$60,000. This insures the

future of Empire. The property, being purchased as it is by a man who never invests unless satisfied that the mines will pay, will be worked systematically and will bring Clear Creek's gold camp to the front. About four ft of snow on the level is reported in Grizzly gulch, Mr. Moore, who is leasing on the Shively mine, has been taking out good pay for some time. The lessees on the Young America, on Red Elephant, now have a fine streak of ore and are running night and day shifts. It is reported that the Snyder lease in the Baltimore tunnel is still paying well, the lessees shipping regularly and the streak increasing in richness and size. Herman Minert, who has been doing deal work on his lode on Kelso mountain, has at last much brighter prospects. After running 150 ft he has encountered nearly a foot of good ore. Messrs. Woods and Walsh, on the eighth level of the White lode, on Red Elephant, have a four inch streak of ore extending the length of 30 ft along drift. The ore mill runs 200 owners.

A TENDERFOOT STRIKE.—I understand, as they are called in Colorado, are usually looked upon as the class who do foolish work and development upon property that gives no showing of ever becoming a producer. Yet the opposite of this idea is many times the truth and the laughing-stock of the experienced miner becomes the bonanza king. A case in point is the recent rich strike made on Red Elephant mountain by C. Koontz, of Empire. Mr. Koontz has been patiently developing his property, without regard to the derision of those who said he has wasting money, and working where no mineral could possibly exist. Last week, in drifting west from the bottom of the 80 ft shaft on the Little Giant lode, he encountered a small streak of mineral that in driving six ft has widened to over eight inches. As development work proceeds the ore body continues to improve, and is beyond cavil, one of the richest and best strikes ever made in Clear Creek country. It will serve also to prove to doubters that Red Elephant is still one of the best camps in the State, and that with development every mine on the hill will prove a bonanza. Mr. Koontz says he feels that at last he has his fortune in easy grasp, and we must admit the truth of it when we remember that a millrun from the ore taken out this week gave returns of 540 ounces silver first-class 260 ounces second-class and 32 per cent lead. Development work will be pushed with vigor, and the lode will soon be a veritable Little Giant.

IDAHO.

LOST RIVER.—*Cor. Wood River Times*, June 11: Your humble servant, took the opportunity of visiting some of the promising mines of this camp. From Alder City our first direction was up Alder creek to the new saw mill being erected by Messrs. Skelton and Ashton. The mill is not running as yet, but the road is completed and the mill on the ground, and will be sawing next Monday a week. From the sawmill we went some two miles farther up the creek, to where Harry Curtis and Fred Roth are camped. Harry possesses an interest in the Black Horse, Wheel of Fortune and Homestake claims. They all show immense croppings of iron, copper, galena and carbonate, and are bound to enrich the boy. And who objects? Farther up is the celebrated Mammoth Mine, owned by Talbot, Peterson, Cannady and McGee. This property is among the oldest in the camp, and carries a continuous body of six ft of carbonate that mills 90 ounces silver and 50 per cent lead. Between the extreme head of Alder and Antelope creeks, Bill Seameids & Co. are said to own a mammoth gold ledge, of an unknown width, that mills about \$20 per ton in gold. Bill was at Alder City last evening with some of the other boys, and before leaving he grew so enthusiastic over his promising success that he agreed to have a 50-stamp mill in operation in 30 days. After visiting some promising lodes belonging to Rose & Harrington, we wended our way toward White Knob creek, passing "Camp Tuscarora" and a wonderful deposit of iron and lead called the Isabelle, owned by Owen & Hall. Here we found several camps, the inmates hard at work and confident. Ed. Kenney has a good location near the Copper King that shows a strong ledge of galena. Messrs. Gary and Lane are here erecting a comfortable log house and shop, and are preparing to do assessment. These boys own the south extension of the celebrated Grand Prize. To the north of the Copper King, Juel Reser & Co. have the Gray Eagle, Jay Gould, Silver Bell, and other properties, all of which show ore from the surface—and high grade at that—the Gould averaging 300 ounces. Near here also are the D. & R. G. Blue Wing, Steamboat and others, that are principally owned by Bill Burnett, of the Battle Ground Station. William is looking for a claim near his ranch above, which if he succeeds in locating without having it jumped will prove a bonanza. He intends working it by both day and night shifts. Dow & Pratt own the Pilot mine, and have a good grade ore and plenty of it. One of the big mines of this district is the Black Daisy, Franklin & Co. owners. They have not less than 400 tons of ore already on the dump and plenty of more in sight.

ORE AND BULLION.—*Wood River Times*, June 10: During the month of May, 1,480,490 pounds (or over 740 tons) of ore were shipped from this point by the Hailey Sampling Works. Two carloads of copper matte from the Ramshorn Smelter were also shipped. The ore carried the usual average of 150 ounces silver and 60 per cent lead, and was therefore worth over \$200 per ton. The total value of the ore and matte shipped during the month, therefore, exceeds \$200,000. There is a considerable quantity of ore and bullion at the various mills, smelting works and on the mine dumps, which are just beginning to find their way to the railroad at this place, the roads having but lately become practicable. The shipments during the current month will probably be twice as heavy as they were last month.

THE MULDON FURNACES.—Colonel Ballantine, Supt., of the Little Wood M. and Smelting Co., and Fulton Haight, Superintendent of the Muldoon and other mines, are in Hailey, but will leave for Muldoon to-morrow. Colonel Ballantine has just returned from Philadelphia, where he went to consult with the trustees of his company. He says he will blow in one of his 40-ton furnaces about the first day of July, and that he will blow in the other as soon as he gets his concentrating works going. These will be obtained here, from the new foundry. After looking over the prices in the East, Colonel Ballantine concluded that he could do quite as well here as to prices, and much better in the way of possible re-

pairs. He expects to start up his concentrating works by the first of August.

LAKE CREEK CLAIMS.—*Ketchum KeyStone*, June 11: The mining outlook of Lake creek is encouraging this year and we are lead to believe that before long that section will be one of our most productive tributaries. It is characterized by large and extensive ledges containing free smelting ores just a little below the usual grade of this region. It is partially owing to this difference in grade and partially to the rude facilities of transportation, and the snows at that altitude, that the Lake creek properties have in general, suffered slow development. But these disadvantages are nothing in the face of capital and enterprise, and the time is close at hand when the Lake creek country will figure conspicuously as a factor in the leading industry. The usual grade of ores in that locality is from 50 to 75 ozs. silver, and 40 to 60 per cent lead. The following prospects constitute the best in that section and are known as the Homestake group.

THE ALPINE.—This prospect is the property of T. F. Shaw, James Moore and T. B. Mulkey. It shows a well formed ledge and has several tons of good ore on the dump. The Alpine is uncovered in many places but not to exceed 10 ft in depth.

THE HOMESTAKE.—Is the original location among the group that bears its name, and is owned by Harry Frost, J. C. Swift and others. It has a 55-foot tunnel, a 50 foot shaft and about 15 tons of good ore on dump. The vein shows as well as any on the ledge.

THE MERKIMACK.—Is owned by Mr. Stow, and is perhaps the best developed lode in the group. It has a 50-foot tunnel with 12 inches of solid ore in the face; 75 sacks of which were shipped two years ago and returned a net profit of 45 ozs per ton.

THE DIXON.—Is developed by a forty-foot shaft and a twenty-foot tunnel. The ore is remarkable in being a little higher grade than that of the others, assaying from 45 to 300 ozs. in silver and from 50 to 60 per cent lead. The whole group is characterized by good walls and fair working ground.

MONTANA.

A GOOD THING FOR TEN MILE.—*Helena Independent*, June 12: Prof. J. G. Murphy has returned from a trip into Ten Mile district, where he has been to get a sample lot of ore to ship East for testing it to ascertain the most economical method of extracting the precious metals. The sample lot of ore consists of about 500 pounds from the Stanton, Basset, Coyne and other mines in that particular group. The ore is silver lead. The present owners of the mines, we believe, are making a move to sell them. They are men of means, and if they do not sell they will work the mines themselves. So, in any event, the mines are to be opened and worked, and doubtless reduction or concentrating works will be erected, as the only point remaining to be settled is to ascertain the most economical method of treating the ore. Prof. Murphy says that since his last visit to the district, two years ago, there has been much improvement both in development and the appearance of the numerous mines of the district.

NEW MEXICO.

SILVER MONUMENT.—*Black Range*, June 13: Work is progressing satisfactorily on the Silver Monument mine. The shaft has been cut through from the tunnel to the surface and ten men are now at work taking out ore and retrimbering in places where the previous work was thought to be insecure. Two car loads of the best ore will be shipped at the earliest date possible. The road to the mine is almost completely and as soon as it is finished there are 200 tons of non-shipping ore which will be brought down to the concentrator. There are several mines in the Black Range which contain bodies of rich ore and which would if worked, help the country greatly and pay a good revenue to the owners. But they lie idle and the proprietors thereof will neither work the mines themselves nor lease them to those who will work them. The Mackey lode, in the Magdalena's, has a shaft of 65 ft, and is very rich in chlorides, native and horn silver. Assays run from 80 to 600 ounces to the ton. The concentrator has added about 900 ft of sluice boxes in which to make a saving of the mineral which may be running away in the tailings. It is expected that considerable time and labor will be required to make a new machine do the best of work on strange ores, but Mr. Castle is fast reaching that desirable point. With the arrival of the new screens, rolls and crusher jaws, there will be a radical improvement in the working of the plant.

UTAH.

REVIEW.—*Salt Lake Tribune*, June 13: The great body of snow in the hills, surpassing that of any former year in many places, makes the opening of the hill roads very slow and expensive this year. Usually at this date the snow is practically out of the way, but it is very much in the way so far this season. The movement of the metals, however, for the past week has been quite active. The receipts of bullion in this city for the week ending June 11th, inclusive, was \$137,554 82; of ore, \$3,700, the first ore receipts for more than a month. The receipts of the week previous were \$113,783 86 in bullion. The shipments of the Horn Silver for the week amounted to 17 cars of bullion, \$51,000. Total product for the year to date, \$977,000. The shipments of Ontario bullion for the week were 34 bars, valued at \$36,909 68, bringing up the total shipments for the year to \$685,648 27. Sales of Ontario stock for the week in New York amounted to 60 shares, on May 31st, at \$200; on June 2d, \$19 00. The Stormont sent up on the 5th three bars of Stormont silver, \$4,150. The Hanauer smelter produced during the week six cars of bullion, \$15,400. T. R. Jones & Co. received four cars Day bullion, \$15,985 50. Nevada ores to the value of \$1,250 were received on the 9th; also one car of Mayflower ore, \$2,450, on the same date.

ECONOMICAL.—*Pioche Record*, June 7: The Stormont Mining Company, of Silver Reef, is working about fifty men. The affairs of the company are being run very economically. When the roads are bad and the teams are unable to haul ore to the mill, the men are knocked off at the mine for four or five days at the time. Close work.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Hagdon or Grant and Old Abe Co., Black Hills also Corliss Pumping Engines, 20x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Ocu. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,760 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

McCaskell's Patent Car Wheels and Axles—Best in Use.

New York Office, Walter McDermott, Manager, Room 32, No. 2 Wall St.

F. A. HUNTINGTON, SAW, SHINGLE, AND QUARTZ MILL MACHINERY.

We Call Attention to the Following Testimonials as to the Capacity and Durability of the Centrifugal Roller Quartz Mill:

SAN FRANCISCO, Dec. 27, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR: The four-foot Centrifugal Roller Mill, bought of you in August, 1882, for the Whittier Gold Mining Company, of Shingle Springs, has given entire satisfaction, both on our own and on custom work, saving from 85 to 90 per cent of the gold in the mill. In conclusion I will say that we are so well pleased with it that Mr. Whidden and myself are pitting one of the same size on the Tohongo gold mine, near Ravenna, in Los Angeles county.

Yours truly, P. A. EASEY,
34 California St., S. F.

FINE GOLD GULCH, Nov. 10, 1883.

Mr. F. A. Huntington, San Francisco, Cal.—
DEAR SIR: In reply to your inquiry concerning the working of your Centrifugal Roller Quartz Mill, I am pleased to say that I run one of them for seven months, doing custom work on different varieties of rock, and that the mill give satisfaction in every respect, and did all that you claim for it.

Yours truly, BYRON JENNINGS.

GARIBALDI MINE, Dec. 17, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: In reply to yours of the 10th inst., I take pleasure in assuring you that your Centrifugal Roller Quartz Mill gives entire satisfaction, and I can heartily recommend it to mining men who want a cheap and efficient crusher. Yours truly, E. I. PARSONS, Supt.

32 WASHINGTON AVENUE, }
SAN FRANCISCO, Dec. 29, 1883. }

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: Having run one of your Centrifugal Roller Quartz Mills on sample lots of rock from more than twenty different mines, I must say that in every instance it has given the best of satisfaction in every particular; and I recognize its superiority over any other mill manufactured. Very truly yours, D. O. MOWRY.

MILLS ERECTED WITH ALL APPLIANCES COMPLETE.

F. A. HUNTINGTON, 45 Fremont St., San Francisco.

CAPACITY AND DURABILITY GUARANTEED.

SEE SAMPLE LOTS OF ORE WORKED.

WHERE A MACHINE CAN BE SEEN IN OPERATION.

CENTRIFUGAL ROLLER QUARTZ MILL.

The work done by the Centrifugal Roller Quartz Mill, during the past two years, on various mines and different kinds of rock, PROVES ALL THAT IS CLAIMED FOR IT, VIZ:

1. The cost of same capacity is not more than one-half that of stamps.
2. Freight to mine one-fourth that of stamps.
3. Cost of erection at mine one-tenth that of stamps.
4. It runs with one-third the power per ton of ore crushed.
5. The wear is less than that of stamps.
6. The wearing parts are easily duplicated.
7. It has a much better discharge, and leaves the pulp in better condition for concentrating.
8. It is a better Amalgamator, saving fully nine-tenths of the gold in the mill; the balance can be saved on plates in the usual manner.
9. It is continually crushing; not like the stamp, using power to suspend it in air ninety-nine one-hundredths of the time and the balance making a thundering noise, and accomplishing comparatively small results. It is as far in advance of the stamp mill as the present method of making flour with improved rolls is over the Indian's mode of crushing corn in a stone mortar.

PATTEN'S CONCENTRATOR.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use; all of which any practical miner will comprehend when seeing it in operation.

SONORA, CAL., Dec. 1, 1883.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: In reply to yours of recent date, inquiring about the Centrifugal Mill which I bought of you, I will say that I have run the mill four months on hard rock; and I take pleasure in adding that the mill has in every way given the best of satisfaction.

Yours truly, J. H. NEALE.

GARIBALDI MINE,
Calaveras Co., Cal., Dec. 17, 1883. }

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: In answer to your inquiry concerning the working of the five feet Centrifugal Mill, bought of you for the Garibaldi mine in Calaveras county, I take pleasure in saying it gives entire satisfaction in every respect, and I only regret that the mine does not warrant the purchase of more of them and the continued use of the one now in operation. Very truly yours, O. B. SMITH.

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: Your Centrifugal Roller Quartz Mill has run on the Whittier Gold Mining Co. property at Shingle Springs, El Dorado Co., Cal., about four months, and it has done good and satisfactory work, a greater proportion of gold remaining in the mill than in the stamp battery. FRED JONES, Supt.

HILBRETH RANCH, Fresno Co., Cal., }
January 11, 1884. }

F. A. Huntington, Esq., San Francisco, Cal.—
DEAR SIR: In regard to your mill (Centrifugal Roller), I have crushed about 500 tons of rock in the mill, and am glad to say that it has given entire satisfaction, and can recommend it to the public as the most expeditious and least expensive method for crushing and milling ore that I have ever seen. Truly yours, THOS. HILBRETH.

JAS. LEFFEL'S TURBINE WATER WHEEL, The "Old Reliable,"

With Important Improvements, making it the

MOST PERFECT TURBINE NOW IN USE,

Comprising the Largest and the Smallest Wheels, under both the Highest and Lowest head used in this country. Our new Illustrated Book sent free to those owning water power.

Those improving water power should not fail to write us for New Prices, before buying elsewhere. New Ships and New Machinery are provided for making this Wheel. Address

JAMES LEFFEL & CO.,

PARKE & LACY, General Agents, 21 & 23 Fremont St., S. F.

Cheap Ore Pulverizer.

There is for sale in this city, by I. A. Heald, American Machine and Model Works, 111 and 113 First street, a Rutherford Pulverizer, an improved revolving barrel crusher, which was only used a few times and is as good as new. It will be sold very much below costs, and miners who are in need of such an appliance for a small mine will do well to make inquiries concerning it. It is suitable for a pulverizing mill for powder or other substances. References as to above can be had upon applying to this office.

San Francisco Cordage Factory.

Established 1856.

Constantly on hand a full assortment of Manila Rope, Sisa Rope, Tarred Manila Rope, Hay Rope, Whale Line, etc., etc.

Extra sizes and lengths made to order on short notice.

TUBBS & CO.

611 and 613 Front St., San Francisco.

Engraving.

Superior Wood and Metal Engraving, Electrotyping and Stereotyping done at the office of the Mining and Scientific Press, San Francisco, at favorable rates.

WORTHINGTON MINE PUMP.

ALEXANDER L. HOLLEY, being duly sworn, says: I am by profession a civil and mechanical engineer. I have been especially employed during the last ten years constructing and managing works for the manufacture of Bessemer steel. I am now Consulting Engineer to the Bessemer Steel Works of Troy, the Cambria Iron Works, the Bethlehem Iron Works, the North Chicago Rolling Mills, the Joliet Iron and Steel Works, and the Edgar Thomas Steel Works. In all Bessemer Works the hydraulic machinery is the most expensive and the hardest worked part of the plant. Any delay or serious derangement in its operation is fatal to the commercial success of the Bessemer process. After extensive acquaintance with the WORTHINGTON ENGINES, and with all such other forms of pumping engines as have been applied to the purposes required, I have adopted it exclusively, and to my knowledge it is adopted in every Bessemer works running or building in America. I have also, for the same reasons, adopted the WORTHINGTON PUMPS for feeding boilers.

WILL CONTRACT TO RAISE ANY REQUIRED HEIGHT SINGLE LIFT with our NEW PATENT MINE PUMP. Recent practical tests in Deep Mines of Mexico demonstrate this to be the BEST MINING PUMP extant. The largest stock of PUMPS for all purposes west of New York at our

PATENTS AND INVENTIONS.

List of U. S. Patents for Pacific Coast Inventors.

From the official list of U. S. Patents in Dewey & Co.'s Scientific Press Patent Agency, 254 Market St., S. F.

FOR WEEK ENDING JUNE 10, 1884.
 299,945.—DREDGE—J. A. Ball, Oakland.
 299,946.—PAPER WEIGHT—C. J. R. Ballard, Orland, Cal.
 300,203.—REVOLVING BOOK STAND—D. D. Bowman, Eureka, Cal.
 300,216.—SAWMILL—P. M. G. Chisholm, S. F.
 300,053.—EARTH BORING AUGER—C. De Mezer, Santa Clara, Cal.
 300,054.—BRICK-KILN—W. H. De Valin, San Rafael, Cal.
 300,056.—HORSE DETACHER—O. Dupas, San Rafael, Cal.
 300,067.—HEADER AND THRASHER—C. Grattan, Stockton, Cal.
 300,250.—STOCK CAR STALL—W. Holden, Los Angeles.
 300,083.—SOLDERING MACHINE—M. Jensen, Astoria, Or.
 300,103.—MILLSTONE DRESSING MACHINE—John Miller, Milton, Or.
 300,281.—EXPLOSIVE COMPOUND—W. R. Quinn, S. F.
 300,142.—HOISTING GEAR—L. & A. Scoville, Oakland.
 300,332.—UNIVERSAL BALL JOINT—A. W. Von Schmidt, S. F.
 300,333.—DREDGING MACHINE—A. W. Von Schmidt, S. F.

NOTE.—Copies of U. S. and Foreign Patents furnished by DEWEY & CO. in the shortest time possible (by telegraph or otherwise) at the lowest rates. All patent business for Pacific coast inventors transacted with perfect security and the shortest possible time.

Notices of Recent Patents.

Among the patents recently obtained through Dewey & Co.'s Scientific Press U. S. and Foreign Patent Agency, the following are worthy of special mention:

HEADER AND THRASHER.—Christopher Grattan, Stockton. No. 300,067. Dated June 10, 1884. This invention relates to certain improvements in that class of apparatus by which grain is harvested, threshed and cleaned in a series of continuous operations performed by a machine which is propelled about a field. The invention consists in a supplemental carrier belt to receive and convey the straw and chaff as they escape from the straw-carrier and cleaning shoe, together with a means for adjusting the same and a shield or guard and directing chute.

Mining Share Market.

The market is still slow, but a move is being made on the Comstock which may result in a more favorable condition of things. At the north end they will soon be ready to begin prospecting at the great depth of 3,210 feet, at which point a station is now being opened in the Mexican winze. It was intended to open this station exactly on the 3200 level, but at that point the ground was a mixture of quartz, clay and porphyry—clay predominating—and too soft for a station. This material is thought to be the east side of the vein found on the 3100 level. While the quartz thus far found is metal bearing, still it is of a low grade. However, the indications are that they will not drift far to the west from the new station before cutting the ore vein.

The Directors of the Mexican mine at a meeting this week adopted the following resolution:

WHEREAS, The 3200 level of this mine has more favorable inducements for ore than the lower of Ophir, Union or Sierra Nevada mines; and, whereas, the sinking of shafts at such depths is attended with great difficulty and expense, now, therefore, be it

Resolved, That the Superintendent of this company be and he is hereby authorized and instructed to make arrangements with the Superintendents of the aforesaid companies referred to, whereby the said adjoining companies shall each bear one-fourth of the expense of immediately sinking the said winze of the Mexican mine to the 3300-foot level, or until the judgment of the said Superintendent deems proper.

At the middle mines the Hale and Norcross folks are regularly extracting and shipping ore from the 200 level. Work has not yet been resumed on the 2800 level, where there is known to be some ore that yields good assays. All work in the lower levels of the middle mines is now awaiting the starting up of the Cornish pump at the 2900 level of the Combination shaft. This pump will be in place and running in about three weeks.

Secure the Reduced Rate.

After the first of April, 1884, we announced a reduction of the price of the MINING AND SCIENTIFIC PRESS from \$4 to \$3 a year to all who would settle up arrears at old rates and pay in advance thereafter. There are some who have not yet taken advantage of this offer, and we would therefore urge all subscribers still in arrears to remit what is due us to this date, at the rate of \$3 a year, and pay in advance for another term at the reduced rates for new subscriptions paid in advance.

MINING SHAREHOLDERS' DIRECTORY.

New Incorporations.

The following companies have been incorporated and papers filed in the office of the Superior Court, Department 10, San Francisco:

PACIFIC COPPER M. Co., June 14th. Location, Arizona. Capital stock, \$5,000,000, in 100,000 shares. Directors, A. W. Heath, Louis J. Hann, John A. Drinkhouse, G. W. Terrill and R. J. Gillett.

REBELLIOUS ORE REDUCTION CO., June 16: Capital stock, \$5,000,000. Trustees, W. B. Douglass, L. A. Gates, A. M. Shields, W. L. Dawson, Joseph Denkselspiel.

WORLD'S ELECTRICAL REBELLIOUS ORE REDUCING CO., June 16. Trustees, W. B. Douglass, L. A. Gates, A. M. Shields, W. L. Dawson, Joseph Denkselspiel.

OLETA M. Co., June 16th. Location, Amador county, California. Capital stock, \$5,000,000. Trustees, E. E. Phelps, C. N. Holmes, D. S. Gellett, T. H. Ganeard, C. S. Bush. Capital, \$500,000.

"First Class and Reasonable"

That is what the best of old travelers and patrons of the ST. JAMES HOTEL, SAN JOSE, say. Mr. Tyler Beach, its proprietor, is one of the early and most enterprising of San Jose's citizens, and, like his hotel, is highly esteemed.

An Easy Binder.

A. T. Dewey's patent elastic binder, for periodicals, music and other printed sheets, is the handiest, best and cheapest of all economical and practical file binders. Newspapers are quickly placed in it and held neatly, as in a cloth-bound book. It is durable, and so simple a child can use it. Price, (size of Mining and Scientific Press, Rural Press, Watchman, Fraternal Publishing Co.'s journals, Harper's Weekly, and Scientific American), 85 cents; postage 10 cents. Postpaid to subscribers of this paper, 50 cents. For sale at this office. Send for illustrated circular. Agents wanted.

Bullion Shipments.

Horn Silver, June 10, \$18,000; Ontario, 13, \$11,706; Hanauer, 10, \$5,100; Mayflower, 10, \$2,450; Hanauer, 11, \$2,350; Ontario, 11, \$4,070; Horn Silver, 11, \$9,000; Hanauer, 12, \$3,050; Horn Silver, 12, \$6,000; Ontario, 12, \$6,122; Stormont, 13, \$3,075; Hanauer, 13, \$5,570; Ontario, 13, \$4,273; Horn Silver, 13, \$12,000; Hanauer, 14, \$2,950; Horn Silver, 14, \$9,000; Ontario, 14, \$598; Hanauer, 15, \$3,300; Day, 15, \$5,000; Horn Silver, 15, \$9,000; Southern Utah, 15, \$5,000.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

IMPORTANT additions are being continually made in Woodward's Gardens. The grotto walled with aquaria is constantly receiving accessions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete, and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

HEINE PATENT SAFETY BOILER,

RISDON IRON AND LOCOMOTIVE WORKS,

Sole Agents for the Pacific Coast, - - - - - Corner Beale and Howard Sts., San Francisco.

Economy in space and fuel. Safety at high pressures. Freedom from scaling. Equally adapted for power and heating purposes. Especially adapted for mills, factories, hotels, stores or any place where safety is a necessity. Will work well with muddy water and any kind of fuel.

TESTIMONIALS.

St. Louis, Mo., Sept. 28, 1883

Messrs. Adolphus Meyer & Co.—GENTLEMEN: We cheerfully certify that the "Heine Patent Safety Boiler" put up by you in our establishment has proved very satisfactory in its working. The chief points of excellence in the "Heine Safety Boiler" are its economy in fuel and space, freedom from scaling, aptitude for power and heating purposes, working equally well with clear and muddy water. We warmly recommend it to all using steam machinery. Yours truly,

ANHEUSER BUSCH BREWING ASSN.

OFFICE OF SUP'T OF ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to your inquiry of September 23, we respectfully inform you that the three boilers built under your patents, under steam since September 25, 1881, at the Alexander Place Depot, as well as the two at Friedrich Strasse Depot, under steam since September 22, 1882, have given good satisfaction, requiring no repairs whatsoever to date. The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the tube caps, the adhesion of scales being fully prevented thereby, and the boilers kept in prime condition.

(Signed): BRAUCKE.

THE ROLLER ORE FEEDER

(Patented May 28, 1882.)

This is the best and cheapest Ore Feeder now in use. It has fewer parts, requires less power, is simpler in adjustment than any other. Feeds coarse ore or soft clay alike uniformly, under one or all the stamps in a battery, as required.

In the Bunker Hill Mill it has run continuously for two years, never having been out of order or costing a dollar for repairs.

MACBETH'S
—PATENT—
STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LEIGH, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq. — Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,
For the Mather Lane Spinning Co. (Limited),
[Signed:] RICHARD T. MARSH,
Managing Director.

THE JENKINS STANDARD PACKING

IS ACKNOWLEDGED BY USERS AS THE BEST in the world. Unlike all other Packings, the Jenkins Standard Packing can be made any thickness desired in a joint by placing two, or as many thicknesses together as desired, and following up joint, it vulcanizes in place and becomes a metal of itself (it is frequently called Jenkins Metal), and will last for years, as it does not rot or burn out. Avoid all imitations, as a good article is always subject to cheap imitations. The genuine has stamped on every sheet "Jenkins Standard Packing," and is for sale by the Trade generally.

\$1,000 CHALLENGE!

PRICE REDUCED,

Jan. 1, 1884, to FIVE HUNDRED
and SEVENTY-FIVE DOLLARS
(\$575.00).

THE FRUE ORE CONCENTRATOR,
OR VANNING MACHINE.

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal.

A machine can be seen in working order and ready to make tests at the office of Hinckley, Spiers & Hayes, No. 2 20 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

Dewey & Co.'s Scientific Press Patent Agency (ESTABLISHED 1860.)

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 252 Market St., S. F.

Number 26.

The Triumph Ore Mill.

A few months since we referred briefly to a trial of a new form of ore mill, invented by Frank A. Hill of this city. Since that time several of the mills have been built and submitted to satisfactory practical working tests. An engraving of the new machine is shown on this page. It is quite simple in operation.

In a suitable bed is a circular V-shaped groove or channel, open at the bottom as shown in the sectional view. In this groove or channel are placed steel rollers or wheels of corresponding shape on their edges. Above them is a large open casting marked, 3 on the large cut, having an inserted V-shaped groove or channel, 4, in which the upper part of the rollers, 5, fit. This channel is formed in the pan or battery, 6.

As the ore falls into the interior, it finds its way into the V-shaped channels, and the broad faces of the rotating rollers, crush it. An end view of the channel is shown in the section.

The centers of the rollers, 5, are open, as shown, to allow the quartz to have free motion all over the machine. The ore is crushed both in the lower and upper channels, as the rollers run free and close together. Around the rollers is a circular screen, 9, through which the pulp passes, the discharge being all around the mill. Below the screen is a circular apron, 7, on to which the pulp falls, and which is provided with amalgamated plates, from this the tailings, etc., fall into the usual sluices.

This upper casting is given a rotary motion by means of an upright shaft and gearing as shown. On top of it is placed a weight which may be changed to give more or less pressure on the rolls. As the weight of this casting rests on the upper edges of the rollers, they are revolved rapidly in the circle in the grooves provided for them, when the casting or frame is revolved by the gears. The upper casting is open at the top and ore which is first passed through a rock breaker is led into the machine by a suitable spout as shown at 10 in the sectional view, water being admitted with it.

The weight, 2, is lifted by a suitable derrick when the weight is to be reduced or a clean up is to be made. The V-shaped channels have removable dies, 8, made of steel. In the section, 1 represents the steel wheels, (cut in two showing end view) showing how they run in the channels; in the same view, 2, 3, shows the opening one and a half inches wide in the channels.

This machine weighs about 3,000 pounds. It is manufactured at the Rice Engine and Boiler Works, 56 Bluxome St., in this city, where one can be seen in operation at any time an appointment is made. There have been many attempts made to perfect a practical machine of this character, and there have been many failures, but Mr. Hill has really produced a machine which, considering the work it will do, the power required, and the cost of machinery, is something wonderful, and those having ores to work ought to investigate for themselves. Mr. Hill informs us that he is able to work over 1,000 pounds an hour; and the capacity may be

increased by adding weights to the machine as described. It will crush 12 to 15 tons in 24 hours and more if required.

In another column are printed some opinions on the workings of this mill, by men of experience in this line, which are really encouraging to the inventor. The machine is at work in several places, and steps have been taken to secure the patent. Those who cannot get the opportunity to see the mill at work can send for circulars, prices and further details, addressing, "Hill's Triumph Ore Mill," care of H. W. Rice, 56 Bluxome St., San Francisco. Mr.

HILL'S TRIUMPH ORE MILL.

Hill proposes to put this machine in the coming Mechanics' Fair in this city, with concentrators and other appliances to properly work ore. Persons having small lots of ore—say five tons or so—who wish it worked, may correspond with him on the subject, as he wishes to get ore enough on hand to keep the mill running.

HUEL AND WHEAL.—The question is often asked as to the meaning of the terms "huel" and "wheal," the one or the other of which is so generally used as a prefix to the names of English mines. By some the two terms are considered synonymous, the former being a corruption of the latter. Both these words had their origin far back in the history of English mining, and what appear to be the best authorities explain their original application as follows: In the early days of English mining the only way of freeing the mines from water was by use of the wheel—a water wheel with a pump or other water lifting appendage; hence those mines which employed this device had the term "wheal" attached as a prefix to their names, which was the common way of spelling the word in olden times. "Huel" is a Cornish term applied to a hole. Hence a mine without a "wheal" for raising water was simply a hole in the ground, and to distinguish it from a "wheal" mine the term "huel" was used as a prefix. There are some, however, who insist that the words are synonymous, and that "huel" is simply a corruption of "wheal."

Blasting and Electricity.

The system of exploding a number of shots simultaneously in rock blasting is making its way slowly into common use abroad. There are many advantages of the system, though there is a prejudice against it, owing to past failures.

But the obvious certainty obtained by using powerful currents and the ease with which such currents may be applied when the works are lighted by electricity, should be sufficient to induce the disappointed to try again. A good ex-

The New Move on the Comstock.

Last week we mentioned the decision of the Union, Sierra Nevada, Mexican and Ophir Mining Companies, to shut down all work, except that on the Mexican winze, which is now at the 3200 level, and will be extended to the 3300, from which point drifts will be run into all the mines of the series. The winze is in easy-working ground, and should it so continue, the connection with the 3300 level can be made within the next two months. The east side of the winze is in vein matter, which is continuous from the 2300 level down. In the other mines of the series pumping will be continued.

The object of this move is to economize and spend money on the most available point only. Superintendent Patton is now more hopeful than he has been in a long time. He says that at a point eighty or ninety feet below the 3100 level a marked change of formation was encountered in the Mexican winze. Much clay began to appear, and in large masses, whereas, above, for several levels, the ground was barren and pinched, with only little starved streaks of clay. The ground in which they are at present at work—ten feet below the 3200 level—looks very much as did that at and about the big bonanza in the California and Consolidated Virginia. There are large masses of clay, and everything shows that there has been a great commotion in the vein. All is broken and tossed about as though by a great upheaval of something below, and it is hoped that this something is an ore body of large size.

The *Enterprise* says the masses of clay encountered are strongly striated vertically, showing that there has been much movement up and down of the rock forming the sides of the vein. These strong scratchings in the smooth surface of the bodies of clay are familiar to all old miners on the Comstock, and have always been found above and alongside of the big ore deposits. Everything indicates that the winze is now in the jumble of clay and rock which forms the top of a large deposit of ore. No such signs of great disturbance has been seen above at any place, and this appearing to be the most favorable point for exploration has decided Mr. Patton and the officers in favor of at once going down to see what lies under the broken material now filling the vein.

Mr. Mackay who has been interviewed, said that this move was in no sense a virtual shut down, but only a concentration of work at one point. He said that if any considerable number of stockholders were dissatisfied with the move, and would guarantee money on the workings of the mines on the old plan, the management would turn the mines over to them and let them work them.

A NEW ACID FACTORY.—The plans and specifications for the largest acid factory on the coast have just been finished. The works will be erected in Marin County and it is intended to furnish all kinds of acids, of which quite a large quantity is used, to the entire coast and Mexico. The estimated cost of the factory will be \$125,000, all furnished by a local capitalist.

ample of the application of the lighting current to the ignition of blasts is cited by Mr. Geo. C. Andre as having come under his notice in Germany. The mine is a colliery, and the surface works are lighted by arc lamps. Underground a stone drift is being driven, and this drift is lighted by incandescent lamps. In the face, from twenty to twenty-four shots are placed, and an electric fuse in each is joined up in parallel circuit by means of bare iron wire and connected with the lighting cables in such a way that the current can be shut from the lamps into the fuses. The result is in the highest degree satisfactory. Misfires are unknown and the effect is wonderfully good. It is estimated that from twenty-eight to thirty-two shots would be needed if fired in the usual manner in succession, so that the saving of labor is in this case considerable, exceeding 25 per cent, both for the labor of boring and the quantity of explosive required.

The Anaconda mine, Montana, from which no ore is extracted except what is absolutely necessary to be taken out in order to extend the drifts, continues to be the heaviest producer in the Territory. It is now yielding about 5,000 tons of shipping ore per month, besides a vast amount which is dumped for treatment at the company's smelter when that vast enterprise shall start up. It is the most extensive copper mine in the United States, and is producing as much even now as the Calumet and Hecla, whose output for May was 2,265 tons.

CORRESPONDENCE

We admit, uncondensed, opinions of correspondents.—E.D.S.

Reasonable Wages and More Employment.

EDITORS PRESS:—You give more interesting, substantial scientific and valuable news in the SCIENTIFIC PRESS than I get from any other paper, and I take several of them. Yet I think you can do much that will increase your popularity with that class of readers who are interested in developments of the mines in the West. I have reference to reaching a certain class who now control labor of miners throughout the mining regions, and by their laws, rules and regulations keep a vast number of valuable mining properties from being worked as they should and would be were they allowed to do so. I know I am treading on ground that is liable to be scorched but I cannot help it. I have suffered with thousands of others who have struggled to keep my interest and mines going in Utah, Idaho, Nevada and Colorado. Of those in Nevada, I have suffered most. How, you may ask? I answer by the arbitrary rules of the Miners' Unions. They dictate to me what I shall do. They even threaten non union men if they continue to work at wages perfectly satisfactory to them and which are remunerative viz., \$3 per day. They threaten to go to the mine and compel them to stop work, and inform the Superintendent they will not be responsible for anything that may happen if he continues to employ them at those wages. They demand \$4 per day, and that they shall become members of the Union. It is one thing to lead a horse to drink and another thing to make him drink. I know that much, but intimidation has been practiced for years in all sorts of ways. Now, how does this prevent development of mines. The properties I have interests in have cost several thousands of dollars to open up; in some of them the ore is low grade, some high—where cost of production is such as to bar its being marketed, it is valueless; but if it could be marketed at even cost, work could be continued in hopes of opening and producing more, so as to become profitable. One fourth the cost of labor taken off would go to the value of the ore, and in our case it would have given more miners employment, and the property would to-day be in my opinion producing ore and giving employment to many miners who have been obliged to go prospecting for want of work. When I say our property, I speak of my own. I can see hundreds of them. Nevada, of all states, is under more arbitrary rule by the Unions than any I know of, in most of the other States, Union wages are about \$3. There are no good reasons why this rate should be demanded in Nevada; provisions and all else are as cheap in many mining districts as in other states where \$3 is only charged. There are many promising prospects in rich districts that are owned by men who have not capital to work them, that would produce some ore of a grade that would pay reasonable cost, and would be prospected if they, the owners, were permitted to control the labor question. But no; the minute a contract is let, it must be investigated by the Union to see if it is up to their standard; if not, quit is the order, the owner must succumb. Virginia City, Austin, Eureka and other old established districts have suffered and now suffer from the arbitrary rules and laws of the Miners' Unions, and the sooner the owners or corporations decide to run their own business in their own way, the better it will be for themselves, the miners and the country. There are cases where it is worth more per day than others, I am willing to admit, but not a universal rule. I would not go to Cœur d'Alene and work for the same pay I could get in Park City, Frisco, Utah or Eureka, Austin, Nevada or Leadville, or St. Elmo, or Gumison, Colorado, for living is more; other things being equal I should do so. I would like to see this matter duly investigated.

ONE WHO HAS SUFFERED.

Mining Camp, — District, June 13th.

IOWA HILL.—A. D. Bowley, of Iowa Hill, was in Auburn a short time last Wednesday, and in answer to a question as to how the times were at the Hill, he remarked: "Well, we are taking out the nuggets." He then, as proof of his statement, proceeded to exhibit several hundred dollars worth of handsome washed gold specimens, ranging in value from about one dollar to nearly \$100, recently taken out by him from the Golden Gate drift mine, located near Iowa Hill. He thinks, without doubt, he is on the famous Succor Flat channel, and the appearance of the gold goes to prove that he is. The old Succor Flat drift mine is working quite a force of men, and is still doing very well. Other mines in the district, he reports as panning out first rate, which gives to Iowa Hill and vicinity, quite an active appearance and an encouraging outlook.—*Placer Herald*.

LOCOMOTIVE BUILDING.—Fifty years ago we imported a locomotive from England as a sample. We now build millions upon millions of dollars' worth for home use and are able to compete with England in all parts of the world. Nearly all the locomotives used in the English colonies are built in the United States.

Cement.

Nearly all cement produced in this country is made from natural cement rock. The Rosendale and Louisville cements which form the great bulk of the production, are natural cements. Portland cement, most of which is imported, comparatively little being made here, is an artificial cement. Besides this, which forms by far the greater part of the importations, we import Roman (a natural cement), Keene's Lafarge, selenitic, lime of Teil and other varieties.

The total cement product of the country in 1882 is estimated by the best authorities at from 3,000,000 to 3,500,000 barrels. Probably the mean of these (3,250,000 barrels) is very near the true production. Of this, \$5,000 barrels, of 400 pounds each is estimated to be the production of artificial or Portland cement. The average value of this is about \$2.25 per barrel at the works. A barrel of natural cement weighs 300 pounds and has an average value at the works of \$1.10. Estimated on this basis the total value of the cement production for the year 1882 was \$3,672,750.

The principal center of the production of American cement are:

First, Ulster county, New York, at Rosendale and in the valley of Roundout creek, where the material of this cement is found in abundance. From the name of the principal producing center of this district, the name Rosendale is given to all natural cement produced in this neighborhood, as well as to all that made from materials obtained here, although prepared for use at other points, as Troy, Brooklyn and Cohoes. The rock used for this purpose is the lowest stratum of the Lower Helderberg group, and the topmost member of the Niagara group. The production of Ulster county is estimated to be between 1,500,000 and 1,600,000 barrels, while that of all New York is placed at about 2,000,000 barrels of 300 pounds each, the spot value of which is about \$1.10 per barrel. The following are the analyses of the Rosendale cements, which although consisting essentially of the silicates of lime, magnesia and alumina, differ materially in their relative proportions:

MATERIALS.		
	Lafarge's Rosendale manufactured by the Rosendale Cement Co.	Portland cement manufactured by the Lafarge Cement Co.
Silica.....	22.77	17.17
Lime.....	34.54	48.28
Magnesia.....	21.85	19.13
Oxide of iron and alumina.....	10.43	10.50
Manganese oxide.....	.37	Trace.
Soda.....	2.28	Trace.
Potash.....	1.35	Trace.
Carbonic acid.....	2.84	3.38
Phosphoric acid.....	.19	
Sulphuric acid.....	1.44	1.20
Water.....	1.59	
Totals.....	99.65	99.96

Beside the natural (Rosendale) cements manufactured in this locality, a small amount of Portland cement is made here.

The second cement-producing locality, in point of importance, is in Kentucky and Indiana, in the neighborhood of the falls of the Ohio. The product is known as the Louisville cement, from the principal center of its production. This is also a natural cement.

Both natural and artificial cements are manufactured to a considerable extent at Allentown, Pennsylvania. Cement is also reported as being manufactured at the following points in the eastern States in a greater or less quantity: Akron and Buffalo, New York; Sandusky, Ohio; Utica, Illinois; Kensington, Connecticut; Cumberland and Round Top, Maryland; Shepherdstown, West Virginia; James River, Virginia; Rockland, Maine; in western Pennsylvania, and at South Bend, Indiana, where small amounts of Portland cement are produced.

Our main supply of Portland and other artificial cements is imported from abroad. There are many varieties of imported Portland differing among themselves in the proportion of their constituents, and in their characteristics of tenacity, strength and hydraulic qualities. Generally speaking, imported Portland cement is manufactured from 60 per cent. of chalk, 30 per cent. of alumina, free of organic matter, and 10 per cent. of silica. Until within a few years all our supply of Portland cement came from England. Recently, however, German importations have assumed great importance, and bid fair to hold a large proportion of the market in the near future. This material is also imported in considerable quantity from Sweden and other Scandinavian countries, and from France. The following is, in brief, a history of the importations from different countries: From 1871 to 1876, practically all importations were from England. From 1876 to 1880, the importations were largely from England, with a gradual encroachment from Germany; while in 1882 the importations from England formed one-half the total amount brought to this country. Three-fourths of the other half were brought from Germany, while the remaining one-eighth came from Sweden, France, and the Netherlands.

The following table gives the total importations during the fiscal years named:

Years.	Quantities, bbls.	Values.
1878.....	92,000	\$184,086
1879.....	106,000	212,719
1880.....	187,000	373,263
1881.....	221,000	441,512
1882.....	337,793	675,587

The values given are based on manufacturers' prices; 40 per cent should be added to bring them up to the prices in this country. The new tariff rate on building cements of all kinds is 20 per centum ad valorem.

Roman cement has been imported almost entirely from Glasgow and London. Of late years the importation of this cement has largely decreased. Lime of Teil is imported mainly from France. The importation of this, Keene's and other cements is comparatively trifling.

Portland, Rosendale and Louisville cements are used primarily for work under water and in all cases where great strength and tenacity are required, as in the foundations of heavy buildings, seawalls, light-houses, bridges, sewers, etc. Portland is used very extensively, also, for cellar floors, sidewalks, and the manufacture of artificial stone. In general it may safely be said that imported Portland possesses a higher degree of tenacity and greater resistance to crushing than other cements, although there may be some American Portland which equals it in these qualities. The great difference in price between the imported and the American Portland on the one hand and the natural American cement on the other illustrates this difference in quality. Roman cement is characterized by setting much more quickly than Portland or American cements, and is hence used for such purposes as repairing leaks, and such minor uses. Keene's is used for the manufacture of imitation marbles, ceilings, cornices, etc. Lime of Teil seems to be of very limited application, and is used mainly in admixture with Portland cements.

While the amount of the importations is increasing with great rapidity, the amount of cement of domestic manufacture is increasing doubtless in an equal ratio. This increased demand, which is largely in excess of the increase in building, is explained by manufacturers and importers as being due to the fact that cement is rapidly replacing lime mortar for ordinary uses of building, especially in large and expensive structures.

Cement in the Rocky Mountain Division.

In 1881 it was accidentally discovered that the lime burned from one of the limestone beds near Canyon City, Colorado, possessed hydraulic properties, and experiments were begun by Mr. N. M. Megrue, of Canyon, with a view to the manufacture of first-class cement. These experiments were continued with but slight success on a large scale. In 1882 works were erected at Denver, and every effort was made to secure the most favorable results. During 1882 about 100 barrels of excellent cement was made, and this was freely tested in various ways, the material satisfactorily standing every test.

Only a small proportion of the rock burned, acted satisfactorily, over 90 per cent being useless for all hydraulic purposes. These experiments have been continued until finally complete success has been achieved. In the first week in May, 1883, the first entire kiln of cement was turned out, and the company are now satisfied of their ability to produce a cement almost equal to the best Portland.

The works and experiments have cost nearly \$30,000, and the capacity is now 100 barrels of 400 pounds net per day. The relative cost of the various brands of cement in Denver is as follows:

Portland, per barrel of 375 pounds net.....	\$7.00 to \$7.50
Louisville, per barrel of 365 pounds net.....	4.00
Denver, per barrel of 400 pounds net.....	6.00

This will make the Denver and Louisville cements cost the same price, 1½ cents per pound.

The Denver cement company expect to fully supply the State of Colorado, and the Territories of Wyoming, Utah and New Mexico with a material which will make excellent and durable pavements and fulfill all the requirements of the best cement.

The Canyon City Iron, Paint and Cement Company manufactured in 1882 2,000 barrels of cement (each 300 pounds net), but its quality has not been ascertained. For the first six months of 1883 the make was 385 barrels. This cement is sold retail at \$4 per barrel.

The source of supply for both companies is the same—the Upper Silurian limestones in Hogback near Canyon city. In the same locality occur beds of infusorial lime and white silica.

Cement on the Pacific Coast.

Fully twenty years ago a bed of hydraulic limestone was opened up about one mile south from the town of Vallejo, Solano county, California, and kilns for burning and a mill for grinding it were erected near the town of Benicia. The rock occurs in seams never more than four or five feet thick, inclosed in a metamorphic sandstone. The belt containing it extends westward across the strait of Carquinez and to the northwest for a distance of ten or twelve miles, in which direction it spreads out over a breadth of several miles. Only at a few points along this belt, however, does the limestone occur in any considerable quantity. The company engaged in beneficiating this rock pay 50 cents per ton for the privilege of taking it out and appropriating it wherever found, paying from \$3 to \$5 per ton for it delivered at their works, which have capacity to turn out about

100 barrels daily. Owing to heavy importations of this commodity, these works have not always been run to their full capacity.

Several years since a bed of limestone suitable for making Roman cement was discovered in the town of Santa Cruz; but the deposit, though apparently extensive, has not as yet been much utilized.

In Oregon, and also in Washington Territory, hydraulic limestone of good quality has been found and works put up for manufacturing it into cement. The discovery of similar limestone elsewhere on the coast has been reported.

The consumption of cement in California is large, much being used in laying the foundations of buildings, for the manufacture of artificial stone, the construction of street, cable roads, dry docks, etc. The importations at the port of San Francisco during the past nine years have been as follows:

Barrels and Casks.		Barrels and Casks.	
1874.....	60,202	1879.....	15,668
1875.....	73,814	1880.....	62,417
1876.....	65,983	1881.....	65,695
1877.....	45,469	1882.....	90,208
1878.....	57,258		

Of late years a large proportion of these imports has consisted of the English Portland cement, which has succeeded, partly owing to low freights, in nearly crowding out the Eastern Rosendale, at one time extensively used. The following are present ruling prices for cement in San Francisco: California, \$2; Rosendale, \$2 75 to \$3; Portland, \$4 to \$4 50 per barrel.

Wood River Mines.

Notwithstanding the fact that very little capital has been brought into this country for the development of its mines, the growth and development of the country has been constant and rapid. In no other ledge mining section, except Leadville, has the mine-owner been able to realize money from working his property without investment in reduction machinery, to the extent that has been done on Wood River. There is no property that has been developed which has not paid for itself, and in many instances, over and over again.

The Englishmen, who recently became the owners of the famous Minnie Moore, are delighted with their purchase—and well may they be, as the developments since the sale have made that property worth twice what they paid for it. Mr. Palmer, one of the new owners in charge, is so well pleased with the country and so thoroughly confirmed in his estimate of the value of our mines, that he is seeking other investments here for himself and associates in Europe. From present appearances English capital will, before the season of 1884 is over, control the principal lead and silver producers of this region.

Numerous extensive and valuable developments have been made already this season, in the various localities from Bellevue to the Smoky. The Bullion mines have never looked so well, and shown so much ore as now. From all directions come reports of renewed activity. Except upon the summit of the highest mountains the snow is gone, and the country is green and beautiful. The summer of 1884 opens more favorably and prosperously than any season in the short history of Wood River, and there is no reason to doubt the prophecy of the *Times* that the product of the country will this year be double that or any previous year.—*Wood River Times*.

GRANITE BLOCKS IN AMALGAMATING PANS.—

A correspondent of the *Engineering and Mining Journal* says: Having for years past been a close observer of the various amalgamating appliances that have been patented and tested to sink into oblivion without a single one fulfilling the requirements, allow me to give your many readers the result of a forced experiment in this line some years since. Two of us got an old rattle-trap mill with both gold and silver tailings to work on percentage. Having little means, we found ourselves with worn-out shoes and dies for our pans. We tried in vain to get some, but failed. I next decided on dressing out granite three inches thick, and using them arastra fashion, instead of iron. The stones were uneven, and our first day's run was anything but a success. The second, however, when the granite slabs began to get properly together, told quite a different story, and the same gold rock that yielded but three dollars a ton in an iron pan, gave us eight dollars between the rocks. With the silver ores we had equally good success. For years I have been hunting abandoned or idle mills, and have got remunerative results where others have failed. I carry a diamond saw, and when a bargain is struck with a mill-owner to run his tailings, I quietly hunt suitable boulders, saw them into slabs and substitute them for iron. They are more durable than iron, cost usually about one-third, and can be had at all places and all times of the year. By putting in a bottom of the cut rocks with Portland cement, the granite will wear to a mere shell without breaking. Where gold ores are contaminated with lead as sulphides, chlorides, etc., this simple appliance gives excellent results, working fully as close to assay as a well-regulated and managed arastra. I have no doubt that others have experimented in this line, but the simplicity of the improvement is the cause of its being overlooked.

MECHANICAL PROGRESS.

Welding Cast Steel.

The welding of steel has always been considered a difficult and mysterious operation, and numerous nostrums, more or less expensive, are in the market for the purpose. A very simple plan is to use ordinary plaster of Paris, or stucco, which is found to answer perfectly. The idea was proposed some time back, but does not appear to be generally known, and it was lately rediscovered by Mr. Benjamin Askew, of Glasgow in a way which constitutes a curious incident in the history of invention. Mr. Askew had a friend who, after much labor, had discovered a composition that served to do for welding steel, and he begged Mr. Askew to try it. Mr. Askew wrote to order a cask on trial, and about a fortnight afterward he went down to the store of the works and demanded if anything of the kind had arrived. The storekeeper told him that something answering the description had indeed come in, but he believed it was common stucco, and thought he would find the invoice to prove it. Mr. Askew, however, inspected the material, decided it was what he was in search of, and carried it off. He tried to see if it would weld cast steel, and it did with the greatest ease. Triumphant he returned to the store, prepared to convince the storekeeper he had really got hold of the steel welder and found that worthy equally triumphant and flourishing an invoice which proved beyond a doubt it was stucco. Somewhat puzzled, and not unnaturally, Mr. Askew applied to his friend and found his mixture had not in fact been sent off, so he was compelled to accept the position that stucco at 3s. per ewt. would weld cast steel quite as well as patent mixtures sold at ten times the sum. He went carefully into the matter, and found that not only was the welding perfect, but that in many cases the quality was improved. Then he took a piece of steel meant for cold chisels, but too hard and brittle to hold its temper. He cut it to pieces, welded these with stucco, and drew them out into cold chisels, which were now found to be of very good quality. A committee appointed by the Scottish Society of Arts, before whom the paper was read, also investigated the matter and fully confirmed Mr. Askew's conclusions, but they drew attention to the fact that the welding of cast steel depends very much on the percentage of carbon it contains. They give the following rules on the subject:

Razor steel, 1½ per cent. carbon; easily burnt and requires skillful handling.
Saw and file temper, ¾ per cent. carbon; should not be heated above a cherry red.

Tool temper 1½ per cent. carbon; can be welded but not without care and skill.

Spindle temper, 1½ per cent. carbon; requires considerable care in welding.

Chisel temper, 1 per cent. carbon; may be welded without much difficulty.

Below this last come the various forms of medium and mild steel, which are easily weldable.

While the welding of steel may thus be said to be with difficulty overcome, the same cannot be said of another operation, very useful in ordinary engineers' practice, namely case-hardening. Experience shows that case-hardening is not possible except with the very mildest descriptions of steel, or rather iron containing not above 0.15 per cent. of carbon. An attempt to case harden steel which is beyond this limit of carbon not only fails but makes it rotten. It is very desirable that this difficulty, and also the failure of steel when welded at a black heat should be thoroughly examined and if possible corrected; otherwise there are certain purposes for which wrought iron is likely after all, to hold its ground.—*Engineering.*

A Process for Softening Iron Castings.

A revolution in the manufactured iron trade is announced from Melbourne, where two local ironfounders (Jenkins and Law) are reported to have discovered a new process in their trade. It appears that an accidental discovery was the commencement of the invention, a fragment of cast iron having been dropped while hot into a water channel, and afterwards broken, when it was observed to be soft and tenacious, instead of hard and brittle, as might have been expected. This phenomenon led to inquiry and experiments, with a view to ascertain the reason of the change. It was supposed that the temperature of the metal and the composition of the water were the principal circumstances which combined to produce the transformation, and after numerous trials the right temperature to which the iron should be brought before immersion was discovered, and also what foreign elements were required in the water. The metal is merely dipped in the bath, not steeped, the required change being physical not chemical, and the ingredients of the liquid are common and cheap.

As patented, the process is briefly as follows: The castings are run in a chill or iron mould, allowed to cool, re-heated in a furnace to a particular temperature, and then plunged into the bath. Thus treated the iron develops a close, tough and comparatively soft grain, so much like that of the average steel that, according to the Melbourne *Argus*, experienced foundries in the colony had great difficulty in believing the metal to be iron at all. By this process it is claimed that the adamant hardness of chilled

castings is removed, and further positive advantages are conferred. Time is saved by the great extension of chill castings for purposes to which their hardness formerly rendered them inapplicable. It is contended that the metal is also made much stronger, a bar that would break with a load of 1,200 pounds under the old system being capable, if made in the new way, of withstanding a strain of 1,900 pounds. Lastly, the soft, tough grain produced by the new process increases the facility of working the metal, with a corresponding diminution in the wear and tear of tools, and a finer appearance in the finished article.

WROUGHT SCRAP CASTINGS.—It will doubtless appear an anomaly to talk of castings from soft steel or wrought iron scrap. Nevertheless, such, we are informed, is the composition of some castings which we recently examined, and which were exhibited in the lobby at the recent meeting of the Iron and Steel Institute. These castings are of Swedish manufacture, being made at the Carlskrona Foundry, Stockholm. Above and beyond what we have stated as to their composition, however, there is a little secret in the manipulation, the result of which is a material embodying all the qualities of good wrought iron or mild steel. Splendid examples of castings were shown, some of which were bent cold into the most trying shapes. This material is said to contain 0.12 per cent. of carbon, to be very easy to weld, and to be practically free from blow-holes. The temper can be varied to suit requirements, and the cost is stated to be the same as that of malleable castings. The quality, however, being greatly superior, renders the new material useful for purposes to which malleable castings could not be applied, owing to their want of perfect reliability. The inventor is Mr. C. Wittenstrom, a Swede, and the matter is in the hands of Mr. Nordenfjelt, of 53 Parliament street, Westminster. Other things being equal, these castings have a wide field of usefulness before them.—*Iron.*

A WIRE PLATING MACHINE.—The Springfield *Republican* tells of a machine that is attracting much attention, just finished, after over seven months' work, and run for an hour or two's exhibition recently at Westfield. It is designed for plating wire with the same facility and ease that the ordinary whip machine plates thread covers on whips, and is to be used for making wire pillows and mattresses for a Philadelphia medical firm. The machine covers a good deal of territory, being 53 feet circumference and 16½ feet across. It has 300 gears and 200 "racers," each of the latter carrying a wire thread. The ordinary plating machine runs only 50 racers, but one has recently been built of 140 racers. This wire plating machine is the largest thing of the kind, and much interest has been felt in its success. It proved perfect in every respect when first started, and as soon as a platform can be arranged over it for the operator's use it will be started regularly.

TEMPERING HAMMERS.—A correspondent of the *Blacksmith and Wheelwright* says: Tempering a hammer is a job that a great many men can not do as it should be done. I was that way myself until last winter when, while traveling in Iowa, I learned from the foreman of a shop there the following method of tempering. After the hammer has been dressed in good shape and everything is ready to temper, get an old coffee pot or some vessel with a small spout attached; heat your hammer to an ordinary heat, and holding it over the spout tub, pour water from the coffee-pot spout into the center of the face until cold. This hardens the center to a greater depth than it can be hardened by plunging the whole face of the hammer into the tub in the ordinary way. The temper can afterward be drawn on the edges.

LOCOMOTIVE LINKS.—Thirty years ago, says *The Blacksmith*, links for locomotives were made of scrap taken anyhow; they were case-hardened. They were all finished previous to hardening, of course, and the slot was of all widths and the surfaces winding in all directions. In such cases they had to be put under a screw-press, and straightened and ground with emery to make them uniform. Once right they wore almost indefinitely without needing repair. Scrap forgings, made of best selected material, are better for shafts than the best cast iron, which has its place only where slow-running shafts, without jar, can be used.

THE MALLEABILITY OF CAST IRON is secured by the abstraction of some of its carbon. As oxidizing agents, to remove the carbon, may be employed, oxide of zinc, anvil scales and brown and red hematites. The iron to be treated is placed upon a bed of such material, the space between the castings being filled up with the same; the whole is then exposed to a red heat in the oven or furnace from 24 to 96 hours. A raw material containing but little manganese and graphite carbon should be used. White pig iron answers well. Malleable cast iron is easily filed and polished, and may be forged at a red heat.—*Sawing Machine News.*

COPPER FOR ROOFING.—It is thought that the decline in the price of copper makes it probable that it will be used as roofing, among other new purposes. It does not require to be painted, like the tin roof, every two or three years, and it is not subject to rust. Even at present prices, though a copper roof might cost two or three times as much as a tin roof, in the end it would be much less expensive.

SCIENTIFIC PROGRESS.

An Important Telegraphic Invention.

At the meeting of the Royal Scientific Society of Canada, opened at Ottawa May 20th and ending May 23d, among other papers presented was a very important one prepared by Mr. F. N. Gisborne, the superintendent of the government telegraph service, in which that gentleman described a new system which he had devised to obviate the evil effect of electrical induction in underground and aerial conductors. A number of diagrams were presented, illustrating the conditions obtained in neighboring circuits; and two or more circuits arranged in the ordinary way, and the same arranged according to his method, were compared. The advantages of the latter arrangement were clearly set forth by a series of experiments made with a section of cable about three thousand feet in length, constructed under his direction, and laid underground between two of the departmental buildings in Ottawa. The cable contains twenty indifferently insulated conductors or wires, which are divided into pairs, two conductors being twisted together in each case. Each pair constituted a metallic circuit, one conductor being used as a "return," instead of the earth plates usually employed. The peculiarity of the invention consists in the twisting of these metallic circuit conductors, as both wires are thus made to occupy an equidistant relationship with respect to any other conductor or pair of conductors in their vicinity. It was explained, that, by this device, a current introduced into a circuit is conducted down one wire, and up the other; and, the position of both wires being the same with respect to neighboring circuits, the inductive effect of the current passing down one wire is neutralized by the inductive effect of the same current passing up the return wire.

It was also theoretically demonstrated that the twisting of the wires of the metallic circuits lessens the effect of introduction of the current upon itself. When the wire of a metallic circuit are laid parallel throughout, the current induced from one wire into the other is in the same direction as the current itself passing in that wire. The effect of the current is therefore prolonged, and retardation experienced in a marked degree, whereas when the wires are twisted closely (say, two turns to the inch) the wires occupy throughout their length a position approaching right-angles with respect to each other, and the induced currents are thereby materially lessened, and retardation rendered less appreciable.

In the discussion which followed the reading of the paper, it transpired that if a conductor were enclosed and insulated within another conductor (as a gutta-percha covered wire drawn through a metal tube), and both conductors were connected at either end so as to form two independent closed circuits, the enclosed conductor might be employed to conduct electrical currents, without any inductive effort being perceived, in a circuit extending parallel with, or in the neighborhood of, the outside conductor. The explanation of this condition is that the outside conductor, which in this case cannot be used as a medium for communication, intercepts the induced currents on all sides of the inducing circuit, and its closed circuit absorbs them. This system, however, could not be made practicable on account of its bulkiness and large first cost.

Mr. Gisborne's construction is much cheaper, and all the conductors form an integral part of the communicating circuits, so that space and expense is economized to the fullest extent. A good deal of interest was manifested in Mr. Gisborne's invention.

[Why could not Mr. G.'s twisted wires be bunched together, with a proper insulating medium, enclosed in iron pipe, and placed underground, for city service, etc.? Would not the twisted wires obviate the trouble of induction which now presents so great an objection to any system of underground wires hitherto devised?—*Eds. Press.*]

THE PLANET SATURN, which has for a long time formed such a conspicuous object in the western sky, until quite recently, has now been lost to sight on account of its apparent near approach to the sun; but it will soon show itself quite as conspicuously as a morning star. It is now at its nearest approach to the earth, and its rings stand at an angle at which they can be best seen and studied. Many important observations have already been made and noted in these columns. A recent number of the *Comptes rendus* contains an account of some very remarkable observations of this planet and Uranus, made by Thollon, Perrotin and Loewyer, at the Nice Observatory, under an extraordinarily favorable condition of the atmosphere. On March 16th the outer of the three rings of Saturn was seen to be made up of three separate rings, of slightly greater breadth toward the ball of the planet; and all of these rings appeared at times to be marked with striae, as if there were indefinite subdivisions. Uranus was observed under similar conditions on March 18th, and its general appearance is described as similar to that of Mars; that is, dark spots near the central portions of the disk, and on the limb of the planet, at position angle 38°, a white spot resembling that seen at the Martial poles. The observers, having taken

care to eliminate a possible deception by the position of their instrument, also recorded a difference of tint of the two hemispheres—dark toward the northwest and toward the southeast bluish white.

ORIGIN OF CRYSTALLINE ROCKS. Dr. G. Sterry Hart, in a paper read before the late meeting of the Royal Society of Canada maintained, in opposition to the plutonic and metamorphic hypotheses of the origin of these rocks, a new one, designated the *crinitic* hypothesis (Greek, "krene" a spring), according to which they were formed, at an early period of the earth's history, by the agency of circulating subterranean waters rising to the earth's surface as springs. He supposes the previous existence of a chaotic layer, the last-congealed portion of a globe consolidating from the centre: which layer, rendered porous, and permeated by waters, gave up to them the materials of quartz and the felspars, after the manner of zeolites, to be deposited at the surface. The action of non-aluminous silicates, allied to pectolite or the magnesium salts in sea-water, was the source of serpentine, pyroxene, etc. The gradual removal by solution from below, of vast quantities of material, and the resulting contraction of the primitive stratum, caused the universal corrugations of the upper acidic or gneissic layer. From the undissolved basic residual portion have come such eruptive rocks as melaphyres and basalts, while granitic and trachytic rocks are softened and displaced portions of the acidic or secondary layer. The author has developed at length this hypothesis, which, according to him, affords a satisfactory explanation of many hitherto unsolved problems in geology.

THE DAVY LAMP.—The philosophy of the safety lamp is best explained by its inventor, Sir Humphrey Davy, who describes it thus: "The principle of my lamp then is that the flame by being supplied with only a limited quantity of air, should produce such a quantity of azotic, or carbonic acid gas, as to prevent the explosion of the fire damp, and which, from the nature of its operations, should be rendered unable to communicate any explosion to the outer air." The surrounding gauze when of a certain mesh, and kept cool, prevents the flame inside the cylinder from coming in contact with the outer gas. The wire gauze should not be more than one twentieth of an inch square. Wire from one-fortieth to one sixtieth of an inch is the most convenient size, and there should be 28 wires or 784 apertures per square inch. The cylinder must have a double top and a diameter of two inches; the object being to prevent too much gas from accumulating inside the lamp and at the same time making it more secure to withstand an explosion.

THE MAGNETIC POLARITY OF IRON. Captain John Hayden, of Bath, Me., author of "The Requisite Nautical Assistant," writes us that as long as forty years ago he practically tested, on shipboard, the influence of upright iron bars or masses of iron on the needle. He says: "Iron rods or bars, in a horizontal position, exert but little force on the compass, but the same amount and form of iron placed vertically produce an immense effect on the needle. The iron rod immediately becomes magnetic when placed in a vertical position, its magnetism increasing with the length of time it so remains, although it manifests no magnetism when parallel with the horizon. This effect on iron is most marked when the rod is held or placed in the magnetic meridian, and in the direction of the tipping needle, which is in this country with the bottom end swung to the north about thirty degrees from the perpendicular."

NEW AND RARE MINERALS.—Colorado has proved itself most rich in new and rare minerals. The latest report in this direction, is from Mr. Hillebrand, who, according to a note in *Science* has recently been busy with the chemical examination of rocks from the Silver-Cliff district. He has proved the existence, at this locality, of several minerals not hitherto known to occur in North America. The results of his examinations also point to the existence, in one of these minerals, of silver in a very rare form, if, indeed, not in a combination hitherto unknown in the mineral kingdom. In March, eleven rock specimens were analyzed, and a number of interesting minerals from Ouray, Col. (some of them probably new to science), were examined.

A NEW TEXTILE PLANT, which received the name "kappe," is attracting considerable attention in Europe. It was first publicly exhibited last year at the Amsterdam Exhibition. It is indigenous to Java; and, when its fibres are carefully prepared, they resemble wool, and, when curled, at a moderate cost they can be used for stuffing mattresses. It can also be spun and dyed; but the fibrous appearance it retains shows that a radical improvement in the method of treating it has still to be discovered. All who examined the fibre at Amsterdam were satisfied of its contingent improvement as a textile material.

INTERESTING BOTANICAL COLLECTION.—It is claimed that the Missouri Botanical Gardens near St. Louis, have a complete collection of living specimens of all the plants mentioned in the Bible.

SAN FRANCISCO:

Staturday Morning, June 28, 1884.

TABLE OF CONTENTS.

ILLUSTRATIONS.—Hill's Triumph Ore Mill, 429.
The Champion Hand Drill, 433.

EDITORIALS.—The Triumph Ore Mill; Blasting and Electricity; The New Move on the Comstock; Huel and Wheat; 429. Close of the Volume; Utilizing Small Coal; Valuable Mines of Pyrites; A Chile Copper Mine, An Old Tunnel; Passing Events; 433. Cable Railroads Abroad; Inspection of Explosives; The Champion Hand Drill, 433.

CORRESPONDENCE.—Reasonable Wages and More Employment, 430.

MECHANICAL PROGRESS.—Welding Cast Steel; A Process for Softening Iron Castings; Wrought Scrap Castings; A Wire Plating Machine; Tempering Hammers; Locomotive Links; Copper for Roofing, 431.

SCIENTIFIC PROGRESS.—An Important Telegraphic Invention; Origin of Chloroform; Rocks; Rare Minerals; Interesting Botanical Collection, 431.

ENGINEERING NOTES.—Distributing Power from Central Stations; Underground Telegraph Wires; A Triple Railroad Crossing; An Immense Dam; The Atlantic and Mediterranean Canal, 435.

USEFUL INFORMATION.—Liquid Bronze; A Machine Horse Cleaner; A Use for Pea Pods; A Variety for Patterns; Grape Seed Oil; Paper from Sugar Cane; Pins and Needles; A Legacy for Aerial Navigation Experiments; A Miner's Pocket Knife, 435.

GOOD HEALTH.—Diphtheria Caused by Over-crowding; Alcohol and the Heart Beats; Fluids and Fat; A Hair Restorer; Cow's Milk for Children, 435.

MISCELLANEOUS.—Cement; Wood River Mines, 430. Alpine County Notes; Mineral City District; The New Boy on Snake River; Bodie Consolidated; Acquiring Mexican Lands, 434.

MINING SUMMARY.—From the various counties of California, Nevada, Arizona, Idaho, Montana, New Mexico, Oregon and Utah, 436-37.

MINING STOCK MARKET.—Sales at the San Francisco Stock Board; Notices of Meetings. Assessments, Dividends and Bullion Shipments, 440.

Business Announcements.

Machine Works—Wm. Hawkins, S. F.
Boilers—Atlas Engine Works, Indianapolis, Ind.
Rubber Boots—E. T. Allen, S. F.
Air Compressors—Clayton Pump Works, Brooklyn, N. Y.
Mining Engineer—X. Y. Z., San Francisco.

See Advertising Columns.

Passing Events.

THE PRESS ends its forty-seventh volume with this issue, an event which we hope our readers will note as it indicates our attainment of a newspaper age representing experience and vigor.

Aside from what we have noted in our usual mining summary there is nothing special to record from the mining regions. The differences between mine owners and miners in Tombstone Arizona still continues, much to the detriment of the camps.

Along the Southern Pacific in this State there have been washouts, and consequent delays, a very anomalous state of affairs at this season in California for what is usually considered a dry region. Floods are recorded also on the Tule islands, due to the swollen state of the rivers. The rain has done damage in some places. The miners are only sorry they can not utilize the abundance of water now flowing.

GOLD HILL MINERS' UNION ELECTION.—The Gold Hill Miners' Union has elected the following officers to serve for the ensuing six months: President, D. A. Curran; Vice President, J. H. McDonald; Recording Secretary, F. L. Clark; Financial Secretary, Thomas Riley; Treasurer, James Quirk; Warden, William Dyce; Conductor, Joseph Fox; Finance Committee—John McGinnis, Sr., John Walters and Edward McGinnis; Trustees—T. R. Fraser, Samuel Hoge, E. O. Leermo, Al. Joy and M. Deegan.

Close of the Volume.

This number of the MINING AND SCIENTIFIC PRESS is the last one of Volume XLVII, and concludes the twenty-fourth year of the publication. Any newspaper which has been published continuously for that many years must have attained a standing beyond question; and more especially is this the case where the publication is a technical one. For all these years has the MINING AND SCIENTIFIC PRESS been the representative of the mining and industrial classes of this coast. It has seen most of the "excitements" begin and end; recorded their discovery, progress and decadence. It has always been the friend of the miner, mechanic, and others of the progressive and industrial classes of the Pacific coast. That its efforts have been appreciated and its mission recognized is abundantly shown by its circulation and its advertising patronage.

The PRESS has not confined itself to the one subject of mining, but has kept track of mechanical and scientific progress, bringing to its readers each week the freshest news of advance in these lines. Illustrations of machinery and mechanical appliances of general interest have been presented, and all those things of special interest on this coast have been described and pictured.

The PRESS has always made a specialty of keeping track of all new and improved metallurgical processes and appliances, and all mining improvements and systems. It has brought all these things before its readers in an intelligent manner, so that they might keep properly posted on all that pertains to their business in every-day life. The current news from various mining regions and districts in California, Nevada, Arizona, New Mexico, Colorado, Utah, Idaho, Montana, Oregon, Washington and elsewhere, has been carefully collected and condensed each week in such a manner as to present clearly the salient facts in as brief a form as possible. Where regions have had a special attraction, suitable prominence has been given them, and everything relating to new discoveries in new fields has been put before the readers.

With all these years of experience the publishers and editors feel that they know pretty well what class of matter the readers of the PRESS want, and in its selection and preparation due diligence and care has been exercised. The present volume has been specially replete with information concerning mineral substances of commercial importance.

The copious index on the last page of the volume will indicate how wide a range of topics has been treated, and will afford an opportunity to the many who file and bind their papers to hunt up any desired subject without trouble.

The publishers have spared no trouble or expense to make the PRESS of interest and value to its subscribers. They propose to continue to do this, and when improvement is possible it will be made. In coming numbers will be found a great deal of value to the mining and mechanical engineers, as well as to miners, millmen, mechanics and others. As we progress here we find that professional men are more willing their experiences should be known, and as more of them become writers there is a larger fund of valuable experience from which to draw. The PRESS has now many readers, but more will be welcome, and with their increase its field of usefulness is widened.

AN OLD TUNNEL.—Tunneling through the Alps is not altogether a modern idea. As early as 1400 the passes over the Alps into northern Italy formed a serious obstruction to travel and commerce, and entailed a heavy expense upon the inhabitants of the valleys upon either side of the Alps. Negotiations were instituted in 1472 between Louis XI, King of France, and some of the mountain authorities, by which a tunnel should be constructed to facilitate travel and commerce over Mont Viso, and between the valleys of the Po and Queyras. This tunnel was first opened for traffic in 1480—a little over 400 years ago—at a cost of 12,000 florins. The tunnel was six and a half feet in height by eight in width. It is now about 250 feet in length, but it is stated that in consequence of frequent land-slides the openings have gradually receded fully 250 feet, so that it must have been originally about 500 feet in length. This tunnel has been frequently blocked, and even walled up with solid masonry, during times of war. It was last cleared out and made passable by order of Napoleon I, since which time it has been constantly open for traffic.

Utilizing Small Coal.

Although in this country not very much has been done in utilizing small coal for fuel by making it into bricks, on the Continent the system is largely practiced. In France, Belgium and other countries, there is not so much waste as with us; but where the small coal is not converted into coke, it is manufactured into "briquettes" or blocks of compressed fuel, which are sold for domestic locomotive or marine consumption. In some cases the economical principal is still further carried out by utilizing the small waste cinders from the locomotives, and also from the gas works, and making them into briquettes. In some parts of France and Belgium, and where stoves or closed fires are used, briquettes made from small coal, agglomerated with clay only, are largely consumed; but with open fires, or where the briquettes are required for loco or marine consumption, they require to be made from coal, agglomerated with pitch.

In only one part of the United Kingdom has the manufacture of patent fuel made any headway—viz., South Wales. That district is exceptionally favored by its geographical position and the quality of its coal; but even there this manufacture cannot compare with that carried on in France, where at one works alone—viz., the Lorraine Patent Fuel Works, the annual production is upwards of 30,000 tons.

The expense of the process stands against it in many places. For the benefit of readers who may be unacquainted with the details of this manufacture, we may briefly explain that the ordinary "patent fuel" is made from small coal and pitch, the usual operation being as follows: After the coal and pitch have been ground and mixed in the proper proportions, this mixture is heated until the pitch becomes plastic, when the mixture is filled into moulds and subjected to a powerful pressure, by which it is consolidated into "briquettes" or blocks, the pitch holding the particles of coal together. In the ordinary method of heating, superheated steam is forced through the coal and pitch while passing through the pugmill or heater. But with steam, even when superheated, there is always some water from condensation, the pitch is not so plastic as with dry (fire) heat, and the briquettes have a tendency to "crack." In France, a considerable reduction has been effected in the necessary proportion of pitch required, by heating the coal and pitch in a horizontal pugmill or box with an open top, this pugmill being enclosed in an arched brick furnace or stove, in which are several fires playing over the coal and pitch, which is kept in motion by revolving knives or blades. This system not only makes the pitch more plastic than by using superheated steam, but the coal itself (more especially with bituminous qualities) becomes slightly plastic from the presence of the tar in the coal, thus uniting much better with the pitch. By this system, the French makers claim to be able to make their patent fuel with not more than three per cent of pitch. The objections to this system are the costliness of the furnaces, the expense of the fires for heating, and the difficulty of keeping the heat at a regular temperature.

A new dry heating apparatus has lately been introduced in England in which an ordinary blower or air compressor is used to force air through a superheating furnace, by which the temperature is raised as required. This superheater can either be fixed at the end of the boilers, thus utilizing the waste heat, or it can be fired separately. By the use of a pyrometer and an ingenious arrangement of dampers this superheater is kept at the proper temperature required; the hot air is conveyed to the pugmill, in which revolving knives keep the coal and pitch in motion, whilst by another ingenious arrangement of pipes the superheated air is forced through the coal and pitch, thus ensuring all the advantages of the French system at considerably less expense in plant and manufacture. The French Minister of Marine has pronounced these "briquettes" to be the most suitable fuel for use in the navy. On many of the leading Continental railways briquettes are almost entirely used for the locomotives.

It is reported that the Chinese miners have struck rich diggings in the Horsey country, B. C., and that white miners on Bridge creek are making an ounce a day by hand. The gold is coarse—the size of wheat grains. Great hopes are entertained at Lilloet of rich diggings.

Valuable Mines of Pyrites.

The two principal mines worked especially for the pyrites which they contain are the Rio Tinto and the San Domingo mines, in Spain. They are both copper mines. The average copper yield of the former is 2.83 per cent. We have no data as to the percentage of the copper yield of the latter. These mines are both very valuable properties. The pyrites yield of the Rio Tinto for 1883 was 1,099,973 tons, 786,000 tons of which were worked at the mine, the balance being exported mostly to England. There is a rapidly increasing demand in England for pyrites from this mine, as more valuable for their double product of sulphuric acid and copper than any which can be obtained elsewhere. So great is this demand that such additional facilities for saving the ore are being set up at the mine as will ensure an annual product of 1,500,000 after the present year. The copper yield of this mine in 1883 was 12,295 tons. The percentage of this mineral is rapidly increasing as depth in the mine is reached, and it is confidently expected that the yield of copper for 1885 will reach fully 20,000 tons. An enormous amount of money has been expended in opening up this mine and in constructing the large plant required to utilize its product. The present mortgage debt of the company is \$12,260,000. The original capital of the company was \$16,250,000, divided into 325,000 shares, at \$50 each, the present market value of which is \$100, or double the original par value. The net product of the mine for 1883 was \$2,248,290, which will be largely increased hereafter by the greater yield of ore which can be raised as soon as the additions to the plant now in progress are completed. The title of the mine was derived from the Spanish government, and the company has in its waste heaps, accumulated under government working, copper, estimated at 42,000 tons, which is being gradually worked over by the company.

The San Domingo mine is small, when compared with its great rival, the Rio Tinto. Still, since the formation of the present company in 1878, it has paid in dividends \$5,475,040, the returns never being less than ten per cent on the capital stock, and going as high as 25 per cent in 1880. This mine produced 382,530 tons of pyrites in 1883, about one-third of which was shipped.

The Tharsis is another quite famous pyrites mine of Spain. In 1882 it shipped 212,218 tons of pyrites, 5,534 tons of precipitate, and 184,059 tons of iron ore, and yielded a profit of \$1,678,380. The Tharsis Company is exceptionally well situated in having no trouble in marketing its pyrites, some of the greatest alkali manufacturers being among its customers.

A CHILE COPPER MINE.—The Puncallillo Copper Co., is one of the few public companies working Chile copper properties. From the late annual report of this mine we learn 57,864 tons of ore were worked during the year producing 6,272 tons of segalas, containing, 2,924 tons of pure copper, a yield of about five per cent from the ore. The cost of producing the segalas was \$840,498, receipts for sale of same \$1,077,018, leaving a net profit of \$235,519. During the past three years, the company has paid \$825,000 dividends on \$1,000,000 capital, has wiped out an indebtedness of \$337,575, and has \$50,000 undivided profits in the treasury. The company is making efforts to reduce the cost by the introduction of crushing and rock-drilling machinery, so that, notwithstanding the low grade of the ore, the high price of fuel, and the low price of copper, it may be able to hold its own.

GOLD IN EGYPT.—An Egyptian correspondent of the London Times writes that for many years past it has been known that large sums of gold are lying hid in Egypt. It is calculated that about \$200,000,000 in bullion has from time to time been imported into the country. About \$30,000,000 of this is in circulation, and it has recently transpired that during the Vice Royalty of Ismail Pasha another \$30,000,000 was secretly transported to Constantinople. This leaves \$140,000,000 unaccounted for, and this sum must either have been absorbed in the gold ornaments of the country or must be hidden away. Should good government bring peace and security to Egypt, this, or a considerable portion of this sum, will return into circulation and assist in the development of the country.

There has been great destruction by floods in Lincoln county, Nev.

Cable Railroads Abroad.

On the 29th of last month the Highgate-Hill Cable Railroad, in London, was opened for public traffic by the Lord Mayor, M.P., who was accompanied by Alderman Sir Robert Carden, M.P., and Sheriff Cowan, in the presence of thousands of spectators. Especial interest was attached to the opening of this line by scientific men, engineers, and others, including the directors and shareholders in the two companies connected with the work, as it is the first cable tramway line constructed in Europe, and is expected to lead to a general adoption of the system in England and on the Continent. In speaking of the opening, the *London Times* says:

"J. L. Robinson, the General Manager of the Patent Cable Tramway Corporation, who have constructed the line for the Highgate Steep Grade Tramways Company, read an address to the Lord Mayor, thanking him for having consented to perform the inaugural ceremony, and pointing out that although this was the first cable tramway constructed in the United Kingdom, the system was not an untried one, having been for more than ten years in successful working in the United States, and that even the colony of New Zealand had outstripped the mother country in securing the advantages of this system of tramway working, upon the inventions of Mr. Hallidie, Mr. Eppelsheimer and others. In the construction of the Highgate cable tramway, which had been carried out on the best and most improved fashion, the directors had throughout had the benefit of the personal supervision of Mr. Eppelsheimer, one of the original inventors. Over a considerable part of the line there was only a single line of rails, which had rendered considerable mechanical skill necessary to adjust the cable in relation to the "grips" upon the cars, so that they might be made successfully to run up and down the line at will. The gradients on this line were not so steep as those found on cable tramway lines in San Francisco, the steepest here being one in eleven, while one in four and one-half had been successfully worked in the American city; but, as affording illustration of the use of the system on a moderate steep gradient, and on curves on a single line, the Highgate line offered to all interested a most useful and instructive example of its capabilities. A procession of half a dozen cars, laden with various gentlemen interested in the day's proceedings, then ran up the hill. Having inspected the stationary engines and other machinery by which the cable is worked, the Lord Mayor declared the line open for public traffic. His Lordship and a large number of invited guests then proceeded to Fairseat, Highgate-Hill, where, by permission of Sir Sydney H. Waterlow, M.P., a *dejeuner* was provided in a marquee on the lawn, over which Sir John Marcus Stewart presided."

This cable road is about the same length as the original Clay street, that is, from Kearney to Leavenworth. With the exception of the length and the grade, which is about 236 feet in the whole length, it is quite different in other respects. Where the Clay street is straight the Highgate road has only about three straight places in it,—one at each end and one where the single line joins the double—about one-third being single and two-thirds double line. There are no level crossings as on Clay street. All stoppages except at the termini are on a grade. The road being sinuous and made up of reverse curves—both the double and single portions—it required much study combined with previous experience to so arrange the direction of the cable in its running and the sheaves which supported and directed it that the curves in both directions could be safely passed and the cable would return to its proper position on the sheaves when a car had passed. Of a necessity a grip had to be constructed especially for this as well as an entirely new arrangement of carrying sheaves.

San Francisco may be proud that one of the oldest cities has not only adopted the ideas of one of the youngest but has utilized the brains of the young city in putting these ideas into practical use. No more difficult locality could have been selected for the purpose of testing this system of railway propulsion than Highgate Hill, and its success will beget many like enterprises in England and on the Continent.

This road commences at the Archway Tavern where the North Metropolitan Tramway cars stop and several omnibus lines also end at this point, as Highgate Hill is too steep for omnibuses or tram cars. This leads up to the old north gate where stands the Gate House Tavern which still maintains a well deserved reputation for its chops and steaks. From this gate there is a charming walk to Hampstead along Caen wood, passing the "Spaniards" the "Pull and Bush" and "Jack Straws Castle," where refreshments for the inner man may be

had, and this new convenience will give many an opportunity to reach a high equal to "St. Paul's" without a wearisome climb. It may be interesting to know that Sir Sydney Waterlow at whose place "Fairseat" a *dejeuner* was provided, married a Miss Hamilton from California, and has taken himself much interest in the construction of this the initial cable road in Europe. "Fairseat" is just opposite the junction of the double and single line of the Highgate Hill Tramway and no more kindly courtesy could be extended than the hospitality of this generous owner.

This road was surveyed and the system of running the cables planned and arranged by Mr. W. W. Hanscom, M. E., of this city, who went to London for that purpose in 1882, and returned last year. The cable is carried around the curves in a different manner from any other cable roads, and is the result of Mr. Hanscom's experience and study in cable railway construction. These features are incorporated in the patents which Mr. Hanscom has lately patented in the United States, and which were patented in England in 1883. The direct construction of the Highgate line has been under the supervision of Mr. Wm. Eppelsheimer the

Inspection of Explosives.

In Great Britain they have Government inspectors of explosives, and they keep a pretty sharp look-out on the powder factories. The inspectors have just issued their report for last year. The inspectors remark that the year has been conspicuous for the numerous and very serious outrages on the public peace by means of explosives which have been effected or attempted. These disturbances have resulted in two material modifications of the law relating to explosives. The most important of these modifications consisted in the passing, on the 10th of April, of the Explosives Substances Act, 1883. In regard to the general operation of the Act of 1875, it is stated as the result of at least one inspection of every factory and magazine which is in active use in the kingdom, that the level of these establishments has, on the whole, been substantially raised. There has not been any retrogression on the part of those factories and magazines, now happily numerous, where a satisfactory standard of discipline, order, and cleanliness, had been already attained, while in other establishments which have hitherto fallen short of the full requirements of the Act, very marked progress has frequently been made, and there is generally a greater disposition to recognize the advantages of that

with 2,045 in 1880 and 1,973 in 1878. According to the returns furnished by the local authorities, in 1883, the number of registered premises in the United Kingdom on the 1st of April 1883, was as follows: England and Wales 16,958, Scotland 1,742, Ireland 686—in all, 19,386. This total shows a considerable increase on the number returned in 1880—viz., 15,669 and still greater as compared with the 1878 return—viz., 13,152. The inspectors have during the year devoted a good deal of attention to registered premises, and have succeeded in inspecting as many as 319 of these places, which is considerably in excess of the number inspected in any previous year. The result of these inspections, taken as a whole, cannot be regarded as satisfactory. The visits have continually disclosed the very gravest neglect on the part of the occupiers of registered premises even to inform themselves as to the law affecting their business, and a still more widespread neglect to observe it. And the prominent cause of this negligence in a matter which so nearly affects the public safety is plainly, the inspectors say, the want of energy on the part of the local authorities in their administration of the law affecting these places. The number of accidents by explosion and fire of which this department has had cognisance during the year was 172, causing, so far as is known, 39 deaths and injuring 109 persons.

The Champion Hand Drills.

A new hand drill, called the Champion, is now being put on the market here, which is quite a cheap and practical machine, and will enable one man to do a great deal of work in a day. It is, in fact, modeled after the power drills, the piston being drawn back by cams, and thrown forward by a spiral spring, so as to give a direct blow with the drill, instead of striking with a hammer. The drill has a throw of two inches, strikes 150 blows and upwards per minute, and is turned easily with one hand and fed forward with the other. An extra crank can be attached, allowing two men to work if desirable. It is attached firmly to a column, and may be worked at any angle up or down that is desired. The whole machine does not weigh over 150 pounds, including the fly-wheel and column. There are very few pieces of mechanism, the whole being compact and strong.

The engraving given herewith shows the drill. A sectional view also shows the position of spring with relation to the drill bar.

From the circular of the Champion Hand Drill Co., the manufacturers the following directions for operating are taken: Set the column in either horizontal or perpendicular position, as preferred, at the proper distance from the face of the rock to be drilled, then attach the machine thereto, by the clamp, at the proper point to give the desired angle or direction to the hole. Let the points or guide rods firmly in the rock and screw them to place tightly, so as to hold the machine rigid between the column and the rock. In doing this the cylinder must be first moved forward on the guide bars as far as possible to prevent the latter from spreading when the points are screwed to the place.

Next, slide the cylinder back far enough to fit the shortest drill into the clutch, and then push the drill against the face of rock and close the feed nut at the side so as to hold the drill against the rock. Attach the fly-wheel and tighten the nut that connects the clamp and cross-head and all is ready (after oiling). Care must be used in feeding up, so as to prevent the collar striking the cylinder head, and to have the cams let go immediately after the click of the ratchet. Turn steadily at about 70 or 80 revolutions per minute.

Each revolution of the drill gives 26 blows and with cross steel (4 points) reduces the rock to a fine pulp. A single bit drill may be used unless the rock is unusually hard, but four points are always best to use in drill machines of any kind. When it is necessary to clean out the hole or change the drill throw open the feed nut and draw back the cylinder. In starting a hole a large drill should be used for a few inches cutting, say an inch and a half in diameter. A hole 2 feet in depth may be run without disturbing the adjustment of the machine, but in going deeper the drill may be quickly released from the clutch and withdrawn for the purpose of cleaning the hole or replacing the drill with a longer one.

When wishing to change the spring, remove the collar from the piston and unscrew the rear cylinder head. The spring may be of any desired tension according to the rock to be worked. The heaviest ones furnished with the drill give a blow estimated at over 100 pounds, and is sufficient for the hardest rock. When the machine is not in use the feed nut should be left open to relieve the tension of the spring. Washers may be used to increase the tension when deemed advisable, by placing them between the spring and cylinder head. For setting the machine for open work, a stout wooden frame, 5 or 6 feet high and wide, can be made cheaply.

We saw one of these machines at work in the basement of Nos. 8 and 10 Pine Street, where it can be examined. It bored half an inch a minute in a dry hole in trap rock. The drill costs \$125. The cylinder is 3x14 inches; piston 12x1½ inches; guide was 3x4½ inches, long, distance between guide rods 5 inches, column, 2 inch gas pipe, weight of machine without column or fly wheel 75 pounds.

THE CHAMPION HAND DRILL.

constructing Engineer of the Clay street and Geary street roads in this city.

MOUNTAINS OF ALUM AND SULPHUR.—In the northern part of Lower California, Mexico, in the eastern part of the Cocopa mountains, bordering the Colorado desert, about fifty miles in a direct line from the Real del Castillo, and forty miles from the Colorado river, are found four mountains; two of alum, one of alum and sulphur, and one of sulphur. The mountain range is from 2,500 to 5,000 feet in height. The deposit of alum fills two of the mountains from base to summit. These immense banks of alum must be two miles in length, by one-half to one mile in width, an analysis of which shows it to be almost chemically pure. Adjoining these two is another of alum and sulphur, the latter forming about 20 per cent of the whole. Just east of this is a large mountain of almost pure sulphur. In it are found streaks, 2 to 14 inches wide, of pure alum. It is estimated that in these mountains there must be 100,000,000 tons of alum and 1,000,000 tons of sulphur. In the coast range west of San Pedro de Martis, near the coast, and about 150 miles south of the Cocopa alum deposits, there are three other mountains of alum of about the same size. The alum is not as pure as the other, but it is free from sulphur.

GOLD DISCOVERY IN NORWAY.—What promises to be an important discovery of gold was recently made near Bergen, Norway. In sinking a lode in search of copper, gold was found at the depth of about 15 fathoms. This lode is composed of quartz, calcspar and clay-slate, intermixed with sulphur and spots of copper ore. A large quantity of vein stuff has been picked out, containing nuggets and strings of gold. From an opening about 150 fathoms south of the sinking above referred to a sample is said to have been taken in which small strings of gold were seen, and upon being assayed gave a product of 13 ounces to the ton. It is believed that a great portion of the country rock will pay well.

striker attention to effective supervision, especially in matters of detail. The total number of factories (under continuing certificate and license) is now 101 (exclusive of "toy firework" factories) being an increase of four on last year, when the number stood at 100. One factory has ceased to exist during the year, and the number of new factories added has been five, making the total increase, as above stated, four. Altogether sixty-three factories have been newly licensed since the Act came into operation—viz.: eleven in 1876; seventeen in 1877; seven in 1878; eight in 1879; seven in 1880; two in 1881; six in 1882; and five in 1883. The under-mentioned explosives have been added to the licensed list:—F C Dynamite, consisting of not more than seventy-five parts by weight of thoroughly purified nitro-glycerine, uniformly mixed with twenty-five parts by weight of a preparation consisting of an infusorial earth known as "Kieselguhr" and carbonate of soda, the said preparation being sufficiently absorbent in quality when employed in the above proportions to prevent exondation of nitro glycerine. Provided that the amount of carbonate of soda present shall not exceed three parts by weight in every 100 parts by weight of the finished dynamite. Metallic blasting fuse, consisting of a pipe or tube of lead, pewter, or other suitable material, containing gunpowder in the proportion of not more than five ounces of gunpowder to every 50 feet in length of fuse. The dynamite trade has continued very active, though the almost complete suspension of manufacture in the Pembrey Factory, consequent on the serious explosions which occurred there in November, 1882, and the necessity thereby disclosed for comprehensive alteration of the system of manufacture, has left the home production of this explosive entirely in the hands of Nobel's Explosives Company Limited, who have found it necessary to extend their manufacturing facilities. The total number of magazines is now 329, being an increase of 9 on last year. Of stores (i. e., small magazines) licensed by the local authorities for quantities of explosive not exceeding 4,000 lb. of gunpowder, or half that amount of dynamite, gun-cotton and the like) the number existing on the 1st April, 1883, according to returns furnished by the local authorities, was 2,108, as compared

Alpine County Notes.

Far up in the very heart of the Sierras our State boasts of a county with attractions quite peculiar to itself. Seemingly wedged in among larger counties that have become celebrated regions of the Golden State—such as Tuolumne, the hallowed ground of the pioneer who in the early days tore up the shining ledges with his pick and shovel, dug "prospect holes" on the green hills, and witnessed the mad carousings of the swarthy Mexicans; or Calaveras, with its mammoth trees—this little highland county has been long forgotten and its resources neglected. Not wholly lost is this gem of the Sierras, for in the rocky ribs of those steep mountains are rich veins of gold and silver, undiscovered because unfrequented, and a wealth of forest which alone would develop it into one of the best counties of the State.

Alpine county is bounded by Eldorado on the north, by Amador and Calaveras on the west, Tuolumne on the south, and Mono on the east, with a strip of its northeastern boundary touching the State of Nevada. It is situated in the extreme eastern part of the State, and just south of that angle of Nevada that juts into the side of California, giving it its irregular shape. It contains 950 square miles of valuable land, the greater part of it still unexplored. Only in the vicinity of the towns along the margin of the lakes and in the mining districts is the land taken up, and therefore far in the hills, but still within comparatively easy communication with the towns, there are thousands of broad acres seemingly offering a fortune with every section, but yet unoccupied, and they are now the uncultured ranges of the sheep herders. But the time is coming when the thousands of the crowded cities will appreciate the mountain homes—if not for their pleasant situation and quietude, they will for the profit arising from the possession of them, and then we shall see the contentious emigrants pouring in and settling over all those green heights by hundreds, and the county will rank as high in abundance of wealth as the neighboring counties, whose resources have been developed.

Forests, Rivers and Valleys.

The surface is mountainous, covered with a dense growth of pine and spruce. On every highland following the billowy hillocks to the valleys, and creeping up again at the rise of mountains, these trees grow to a great size, and are magnificent specimens of timber. The highest elevations are about 10,000 feet above sea level, and then the mountains gradually sink into the foothills that border on Nevada and the great plain of California. There are several peaks of the Sierra; the highest are Silver Mt. and Round Top. The former, a few miles east of the center of Alpine county, rises above sea level to the height of 10,931 feet, and the latter, in the northern part, is about the same height.

They being formed by volcanic action, of course there is a great deal of lava in their geological composition; besides, there is quartz and granite.

In these high regions are the headwaters of the Stanislaus, Mokelumne and Carson rivers, the first two important tributaries of the San Joaquin and Sacramento rivers. They flow through deep canyons between high walls of rock; fed by numerous torrents, dashing down the steep descents, they are ever swelling, until they reach the great plain. The Stanislaus rises in the watershed, and is formed of two forks. The north fork flows northwest, and forms part of the boundary between Tuolumne and Calaveras, and the south fork flows west into Tuolumne, where the two unite ten miles north of Sonora. Thus the water supply is plentiful for mining, irrigating and manufacturing purposes. It flows through deep arroyos, down the steep declivities with a force powerful enough to move heavy machinery and, moreover, there is an exhaustless supply through all the dry months, from the summit's fountain of melting snows. In many places it, dashes over precipices, thus forming miniature cataracts, and the roar of the falling waters can be heard a long distance through the gorges.

The valleys are comparatively deep, sinking abruptly from all sides of the surrounding mountains, and having few lesser elevations, between their centers, and the great mural ranges. They are covered with heavy forests of pine, with an undergrowth of sage and chaparral, and carpeted with luxuriant growth of grass, which is tall and green through all the summer. In places where the soil is cleared of its native brush, and trees these valleys yield a fair harvest of grain. The cereals do well on the hills, too, when they are not rocky and steep. On the heights, grass also grows in rich abundance, from base to snowline, affording provision through the dry season, to thousands of sheep that migrate from the plains every year. In the south is Hermit valley, the largest in the county, and in the north is a smaller valley, but a somewhat higher one than the former. These are the two principal tracts of lowland, but besides there are many little vales, walled by solid banks of rock into the innermost heart of the mountains.

In the hollows of these grassy valleys there is a number of fresh water lakes, receiving and discharging the pure cold volumes of water from the summits and still lying tranquilly in the rich sunshine as if they were sheets of solid crystal. But the quiet ripples teem with

millions of trout, and in all the streams fish abound.

Mineral Resources.

As for minerals Alpine is indeed possessed of a treasure-hox buried beneath its soil. Gold and silver are most abundant, with slate and copper in small quantities. The gold and silver lie near the surface in ledges of metal-bearing igneous rock or quartz, and usually in the hilly regions. The veins, or leads after running some little distance on or near the upper strata gradually dip and continue on a slight incline into the hillsides, thus making it necessary to tunnel considerably where mining is extensively carried on. Hydraulic mining is convenient on account of the abundance of water, but this is not the usual method, however; blasting and vein mining being preferred as a quicker mode and because the veins are numerous.

The general geological structure of this region is somewhat varied. There is a mixture of basaltic lavas, quartz, granite with slate on the water channels. The violent upheavals and constant action of water have torn up the bedrock in many places so that the general formation can be read as from a book, on the precipitous walls of rock and in the deep canyons worn by the streams.

Climate in this county is healthful and delightful. The air is so clear that distant objects appear distinct through its pure medium and consequently it is free from all poisons and impurities. There are frosts in the early months and snow-storms in the highest portions, but the valleys are protected from heavy snows and thus they secure a more agreeable temperature. In summer the sunshine pours in golden floods over all the peaks and hollows, making it perfect spring-time here when all balmy breezes, mild sunshine and greenness have forsaken the plains below, leaving them parched and dry. The mean degree of temperature in the valleys is about 58° Fahr.

The Towns.

The county seat is Marbleville, situated in the north eastern part and one hundred miles east by north of Sacramento. It is a prosperous little place and three or four saw mills keep it lively all the year. There is some mining going on at this place but not so much as in other towns. The houses are built of pine lumber neatly painted; there are two or three stores, two hotels, a school house—but no court house as yet—and also one Odd Fellow's Lodge.

Monitor is over the summit, that is on the eastern side of the mountains. It is much like the other towns, being, perhaps, more of a business center, and it boasts above others of the publication of the Monitor *Argus*, edited by P. W. Parker. It is a sprightly little paper and considering the population has a wide circulation. There is here about the same number of stores, hotels and public buildings as in other towns. There are rich mines in this vicinity, both of gold and silver, and they keep one large quartz mill constantly in motion besides several smaller ones within the circle of a few miles. The Olympic, I X L and Isabella mines are all near Monitor and yield good paying ores. There is a great deal of tunnelling about the town.

Silver Mt. is built at an altitude of 7,000 feet above sea level, near the east base of the Sierras. There are silver mines here, and consequently the place presents an appearance quite the same as other camps. The machinery and works necessary for carrying on mining operations, quartz mills, tunnels, shafts, sluices and piles of ore indicate that good paying veins have been struck.

THE SNAKE RIVER PLACERS.—These mines are exciting so much interest at present that whatever relates to the working of them is worthy of notice. The new method of concentrating appears to be attracting most attention. It is thus described by a practical miner: "It consists of a grizzly 20 feet long and 2 feet wide. Under this is a sluice box to catch the fine gravel that falls through the grizzly, as the gravel is washed over it from the bank. The grizzly has a fall towards the river of 2 inches in 16 feet, and the sluice under it about 10 inches the other way, and conducts the fine gravel and water back to the rear end of the grizzly, where it enters a cross sluice, running at right-angles to the grizzly, and extending 10 feet to the right and left. Thus we have a sluice thirty inches wide and twenty-two feet long. This sluice is divided by partitions into four different channels, and the channels are so arranged as to conduct the fine gravel and water on to aprons. These aprons are sluice boxes, made of wood or iron. This was of the latter material, nicely placed on a wooden frame, and are sixteen feet long, eighteen inches wide, and have a fall of two inches in sixteen feet; the sides of these aprons are from four to eight inches high, to suit the ideas of the miner. In the bottom of the sluices are placed gunny sacks, held in position secured with buttons. Now, since there are four of these aprons on either side of the grizzly and running parallel to the sluice, it will be readily seen that the fine gravel which passes through the grizzly is divided into eight equal portions, one portion passing over each apron where the fine sand and gold is collected in the gunnies.—*Boise Statesman*.

RECENTLY a multitude of cut-worms invaded the twenty acre vineyard of L. H. Ormes, ten miles west of Phenix, A. T., and before anything could be done, stripped the vines of every leaf and grape.

Mineral City District.

A correspondent of the Salt Lake *Tribune* writes as follows: "You have of course heard of the new mining camp in Washington county, Idaho, known as Mineral City, and hence it will not be necessary to enter into any long description of its location. Suffice to say it is only eighteen miles from the end of the Oregon Short Line track, one-half the distance being over good wagon road, which will soon be completed over the entire distance. Not being a practical miner nor a professor in mineralogy, I will not attempt a description of the practical workings of the different claims, nor a descriptive analysis of the ores taken therefrom. All we need to know about them now is that they are rich in silver and contain gold enough to make the bullion considerably better than pure silver, as will be seen hereafter.

This, like all new silver camps where none of the claims are developed sufficiently to prove them valuable, was looked upon by men representing capital with a good deal of skepticism; while on the other hand, the miners holding the claims, believing them to be rich, were unwilling to part with them for anything short of a "fancy price." The natural consequence was that capitalists declined to invest, development has been slow, and the camp has not received the attention it deserves.

Last fall Mr. D. Hagerty, from San Francisco, visited the mines and remained there several weeks, during which time he made a careful investigation of the ores, formation and general topography of the country, and satisfied himself beyond a doubt that the precious metal was there in good paying quantities. He then completed arrangements with Messrs. Boggs & Landy of the Black Maria mine by which he was to put up a mill and work their ore at a stated price per ton. In March he had a ten stamp mill on the ground, and started it up about the 1st of April. The first six tons of ore put through the mill yielded a bar, or brick of bullion weighing thirty-five pounds, valued \$765, an average yield per ton of \$127.50, a pretty fair showing for the first batch of ore worked in the camp. The mill is now being run to its fullest capacity, and with results even more flattering than the above. Naturally they are learning something every day about treating the ore, and of course are gradually improving the results. Mr. Hagerty expects now to double the capacity of his mill before another winter sets in.

Speaking of winter let it be remembered that winter in this region is not like it is in most mining camps on the coast and work can be carried on without hindrance the entire year.

The camp has merit, which is being proven every day, and will soon assume its place in the list of leading camps on the coast. Nor is the Black Maria the only camp deserving notice. There are the Black Hawk, Daniel Boone, Jolly Traveler and a score of others which for the amount of work done on them are showing up equally as well and will no doubt show as good a record when put to the trial, and you may expect soon to hear glowing accounts of them, now that that the enterprise of Mr. Hagerty has broken the ice and proved successful.

The New Bar on Snake River.

George Little writes to the Salt Lake *Tribune* about the new bar on Snake river, below Caldwell:

On the Snake river, 10 to 15 miles west of Caldwell, some 2,500 claims have been located as placers. They prospect excellently in fine gold, in some instances showing many hundred colors to the pan, and it is estimated by experts, considering the fine water facilities and dumps, especially on the west bank of the river, that at least \$15 per day can be averaged to the man by using the grizzlies, sluices and burlaps. These mines would, without exaggeration, afford employment for a thousand men or more at present, leaving out what the future may develop. The Manhattan bar, about the richest on Snake river, with a good water right of 5,000 inches, and a 14-foot dump at river, has been thrown into a stock company. Fifty-three and one-third acres, or one-third of the 160, is offered for sale at \$5,000, including a one-third interest in the ditch, to enable the owners to open and operate the mine on a big scale. I think this is a splendid investment for any party or parties who desire to speculate in a sure thing, as it is very probable that each machine placed on the mine at a cost of, say \$300, will net a profit per day of from \$50 to \$100—not less than \$50. Now comes the fact that within two days exceedingly rich placer gold diggings have been struck three miles below Caldwell, in Boise River valley, and extend 12 miles down. Water is running over the ground, and about 100 claims have already been located, many of the locators having already commenced vigorous work. Many and astonishing discoveries are expected soon in this rich gold valley. The town, of about 500 people, is on the Oregon Short line, 146 miles west of Shoshone, and has an altitude of 2,300 feet. The country around is settled to a great extent by farmers; the soil is very rich and productive, producing all kinds of grasses, small grains, and every description of fruits in abundance. The climate is delightful the year through. There is room for thousands of farms more than we

have, the land being open to entry. Irrigating ditches are being built all over the land.

We have two schools and a fine church in town. All kinds of business is represented here, and the merchants are prosperous. Good hotels furnish board and lodging very cheaply. A branch railroad is just being commenced, leading from here to Boise City, 32 miles up the Boise river, which will materially aid our town, and give us an impetus that will carry us along to success and a large, thriving town or city.

Bodie Consolidated.

The annual meeting of the company was held last week. The attendance was specially large on account of the report that the control of the company was to be contested. The Lent faction was headed by the Secretary George W. Sessions, W. P. Willard, Will Burling, James Coddington, Archie Borland, Senator Stewart and George Ives. The interests of the opposition were looked after by Mr. Kelly of the Justice and Mr. De Greayer. On calling the roll it was ascertained that there were present in stock and proxies 72,477 shares—49,749 being the San Francisco representation and 22,628 from New York. The weakness of the opposition was apparent from the start; all the heavy San Francisco proxies and votes went to the old officers. The Nevada Bank voted through George Grant, 10,070; Dr. Fox through Mr. Gillen, 2,670; E. A. Richardson for the Bank of California, 1,205; George T. Marye & Son, 3,945; S. B. Wakefield, 455; Nat Stein for the Anglo-Californian Bank, 1,600, and W. H. King 9,377, all these were for the Lent party and the whole of the New York vote, and there was little left. The largest vote was Mr. Hofer, a Carson capitalist, with 2,500. A resolution was then offered by George Ives and seconded by Archie Borland, that all the acts, contracts, sales and disbursements made by the officers for the past year be hereby ratified and accepted—passed. The following trustees were nominated and elected by the old board, namely: W. H. King, J. L. Browne, A. Borland, G. I. Ives, Jos. Clark, W. P. Willard, Thomas Brown.

The total indebtedness of the company today, June 16, 1884, is \$4,500 and the cash in hand \$146,933 03 being equal to a net two dollars per share for all the stock issued—this is the largest bank credit of any Mining Company to-day on the Pacific Coast. At an adjourned meeting, the following officers were elected to serve for the ensuing year: W. P. Willard, President; Jos. Clark, Vice-President; G. W. Sessions, Secretary; Bank of California, Treasurer; John Kelly, Superintendent.

Acquiring Mexican Lands.

Real estate of all kinds, other than mineral lands, can be acquired by foreigners or any nationality residing and domiciled in the Republic of Mexico by the same title and under the same laws and provisions that the municipal authorities have established for Mexican citizens, with the following exceptions, viz.:

First—For a foreigner to acquire landed property within a zone of twenty (20) leagues of any boundary line, a special permit must have been previously obtained from the President of the Republic.

Second—Foreigners cannot acquire real estate within five (5) leagues from the shore line of the coast without a special decree authorizing the same.

Third—Forfeiture to real estate acquired by foreigners takes place for the following reasons and under the following conditions, viz.:

(a) Should he absent himself with his family from the country for two (2) years without a permit from the Government.

(b) All real estate so acquired is non-transferable to non alien residents either by sale or inheritance, or in any other manner with out complying with the following requirements, viz.:

The property must be sold in conformance with the laws regulating such sales and its proceeds delivered to the alien; deducting ten (10) per cent to apply to expenses incurred.

(c) Should a foreigner acquire public lands by denouncement (the extent of which in no case can exceed twenty-five hundred (2,500) hectares) he would lose his title to the said land if he does not keep one inhabitant on each two hundred hectares for four months in each year.

(d) As soon as an alien acquires real estate (landed property) he contracts the following obligations under the provisions of this law:

First—To be law-abiding; to submit to all laws enacted relating to transmission and use of said lands and to the decisions of the Court in all matters.

Second—to pay his pro rata of all taxes legally levied on landed properties.

Third—to personally contribute to the preservation of public peace and tranquillity, excepting always disturbances that arise from political revolution or civil war.

N.—Special laws govern the mineral lands and mines of the Republic.

THREE THOUSAND employees of the worsted mills at Bradford, England, have struck for higher wages. The stone masons of Bradford also struck.

ENGINEERING NOTES.

Distributing Power from Central Stations.

Mining Journal: The notion of distributing power from central stations to the workshops of small users, as they are called, is gaining ground in England, and there is an evident determination to wait no longer for the promised transmission of power by electricity. In London, there is a scheme already partly completed for supplying hydraulic power to city warehouses; and in Birmingham, there is a scheme for supplying motive power by means of compressed air that awaits the sanction of the corporation. It is calculated that the cost of the compressed air would be about the same as gas used in gas engines; but there is this advantage that the compressed air could be utilized in the engines now driven by steam. Out of two hundred and seventy small-power users who have been consulted, nearly two-thirds have expressed their readiness to take the compressed air; and if the scheme can be successfully worked, it will tend to materially reduce the smoke nuisance and the number of boilers, all of which are liable to explode. It is not altogether an easy matter to lay down a series of mains and supply compressed air to the workshops of a given district; but so much has been learned during the recent boring operations connected with the great Alpine tunnels, that it is quite possible to lay on a supply of compressed air, which could be turned on as required by means of a tap. There is one great advantage in the scheme, besides the abolition of the smoky furnace—and that is, that the "exhaust," instead of being very much of a nuisance, would assist in the ventilation of the work-rooms, and in some trades would be of special value in connection with certain processes.

UNDERGROUND TELEGRAPH WIRES.—The problem of laying telegraph wires underground is being solved. In Montreal ten wires were buried last November, and thus far have worked, it is said in a faultless manner in telegraph and telephone service. They are claimed to be equally adapted to electric light purposes. The wires, insulated with a coating of woven thread covered with wax, are laid in a wooden box two feet below the surface of the street. The bottom of the box is coated with a mixture of silica, rosin, linseed oil and paraffine boiled together, which is applied warm, but when cool becomes as hard as a stone. The wires are also drawn through the mixture, and the box, after they have been laid in it, is filled up with the material. The theory is that when the box decays and disappears the stone composition will remain and protect the wires for an indefinite period.

A TRIPLE RAILROAD CROSSING.—According to one of the railroad journals, three heavy steam railroads crossing one above another at the same spot will be one of the curious freaks of railroad construction in Pittsburgh. This coincidence, as it might be termed, is formed by the lines of the Pennsylvania railroad, the Junction railroad and the East End road all coming together in the narrowest part of a narrow valley. The Junction road will pass through a tunnel extended under the road-bed of the Pennsylvania, and the East End line will be continued over an iron bridge at the same spot. Thus, while a through passenger train may be flying eastward on the Pennsylvania road, a heavy freight train may be thundering immediately under it toward the north, and at the same moment a way accommodation train passing south in mid-air.

AN IMMENSE DAM.—A French engineer in Brazil has lately been selected to construct what will probably be, when completed, the largest dam in the world. The dam will be 940 feet long by 58 feet high, and two smaller ones will close side depressions. This work will, it is calculated, back the water over 1,500 acres, and retain 14,000,000 cubic meters of water, sufficient to provide for all the cattle of the regions during three years, and for the irrigation of 5,000 acres of flat bottom land alongside the river bed below. The rivers of Ceara flow in the wet season alone.

THE ATLANTIC AND MEDITERRANEAN CANAL.—Late reports from London say that the scheme for a canal from the Atlantic ocean to the Mediterranean sea, converting the Iberian Peninsula into an island, has been revived. A contract has been signed between the founders of the scheme and the contractors of the Suez canal for a canal capable of taking the largest vessels through. The founders have asked the French Government for a guarantee of £400,000 yearly to begin from 1889, when the works are expected to be completed.

THE NARROW GAUGE RAILROADS OF INDIA are of the extreme narrow-gauge character. On one of the principal ones the track is only twenty-four inches wide. It is said that the cars are of the same Lilliputian dimensions, being a trifle inside of five feet wide by eight in length. We have no data before us in regard to the proportion of narrow to wide gauge which has been built, or as to the width of the wide; but the annual extension of railroads there is quite important, although it has fallen off considerably during the last two years. Only 373 miles were constructed in 1883 against 726 in 1882 and 838 in 1881.

USEFUL INFORMATION.

LIGHT BRONZE. Attempts have often been made to produce bronze colors on non-metallic objects, but these have hitherto required a prior preparation of the surface, and the paint is, moreover, expensive. A cheap and effective bronze or metal-lustred paint has, however, been discovered by Mr. Septimus Furse, a decorative artist. The new paint has twelve distinct colors from red to blue, with any number of combined tints. Its metallic lustre is very striking, and it can be applied to porous, soft or hard surfaces with equal facility. Any unskilled person can apply it, as it is not thick. Wooden platters can be readily gilt by its means; furniture wood, organ-pipes, plaster of Paris statuary, or iron work of all kinds can be made to resemble the more valuable metals with one or at most two coatings. The paint is preservative as well as artistic. While upon this subject we may mention a new process of mineral painting, which has been brought out in Germany by Herr Adolph Keim, of Munich. Specimens of the work were purchased at the recent Nuremberg Art Exhibition for the Architectural Court of the South Kensington Exhibition. The work can be executed on glass, stone, tile wood or canvas, and consists in tracing the outlines on a ground kept moist by spray, and filled in with moist colors fixed by repeated spray of potash water-glass; after which carbonate of ammonia and benzine are applied to the surface.

A MACHINE HORSE CLEANER. A patent has been recently issued for a device for cleaning horses, which is described as follows: A sheet metal box, having a cover provided with a handle, has a transverse slot in the bottom. In the slot is a brush mounted on a shaft, on each end of which is a small wheel, against which rest two larger wheels, mounted on shafts journaled in the sides of the box; these shafts carry links, at the middle of which the brush shaft is journaled. The rims of the wheels are made of rubber. The cleaner is held in the same way as the common horse brush, and as it is rubbed over the animal's skin the large wheels are revolved by friction, as they project slightly from the bottom of the box. This imparts a rapid motion to the small wheels, and the revolving brush sweeps the dust, etc., into the box, from which it can be removed after the cover has been taken off.

A USE FOR PEA-PODS.—The *Baltimore Trade Journal* challenges science to tell what can be done with empty pea-pods. In decay they give out a strong alkali that destroys vegetation, so that they cannot be used as fertilizers and they have to be dumped in the Bay. Yet there must be value in them when fresh. The French people scald such pea hulls, then remove the silicious skins with which they are lined and make an edible dish of them. They contain sugar in no small amount, and probably if properly treated would be as palatable as common string beans. Perhaps in the future when this country comes down to the determination to live as cheaply as any other nation on earth, some genius will find it more to advantage to can the hulls than the peas, as cheap food for the lower classes.

A VARNISH FOR PATTERNS.—A varnish has been invented in Germany for patterns and machinery. It dries, leaving a smooth surface almost as soon as it is applied. It is thus prepared: Thirty pounds of shellac, ten pounds of Manila copal, and ten pounds of Zanzibar copal are placed in a vessel, which is heated externally by steam, and stirred during from four to six hours, after which 150 parts of the finest potato spirit are added, and the whole heated for four hours to 67 degrees. This liquid is dyed by the addition of orange color, and can then be applied as a paint on wood. When used for painting and glazing machinery it consists of 35 pounds of shellac, five pounds of Manila copal and 150 pounds of spirit.

GRAPE-SEED OIL.—In Italy grape seeds from the wineries, are utilized by the extraction of oil which they contain, which is chiefly used for illuminating purposes. The extraction is principally effected at Modena. It has also long been used for similar purposes in Germany and the Levant. Thirty-three pounds of seed yield about 13 quarts of oil (or about 18 per cent). The seeds of white grapes yield less oil than those of the dark variety, and young vines are said to be more fruitful in this respect than older ones. As to the French varieties, the Rossillar, Aube and Hernalt seeds yield 2 per cent more than Bordeaux seeds. The color is a golden yellow, and the oil loses about 25 per cent in purification.

PAPER FROM SUGAR CANE.—Paper is now made from the waste or refuse of sugar cane, after the juice has been expressed from it. The business promises to be the beginning of an important manufacturing enterprise. It will, no doubt, take rank with the recently introduced enterprise of manufacturing oil from cotton seed.

The discovery of the process of manufacturing cotton seed oil converted what was a useless into a valuable article, and added to the manufactures of New Orleans an industry which, in its production, the number of men employed and the profit, is the most important in the city. This new fiber manufacturing company may

thus mark the beginning here of a valuable and important industry. The material at its command is practically inexhaustible, and will mount up in the millions of tons. The Louisiana Fiber Company has been formed to raise a working capital of \$100,000 and erect a first-class pulp and paper mill, adapted to this new process of making paper from bagasse.

PINS AND NEEDLES. The manufacture of needles and pins constitutes one of the most important as well as flourishing industries of Germany. The 8 factories of Islerlohn alone consumed in 1882 no less than 600 tons of steel wire, employing a working force of 1,500 hands, of whom 800 are males and 700 females. The works are driven by 7 steam engines and 4 water wheels of 250 horse-power.

A LEGACY FOR AERIAL NAVIGATION EXPERIMENTS.—Charles F. Ritchel, of Bridgeport, Conn., who tried to invent a flying machine, will get \$100,000 to perfect the invention with from the estate of Maxwell, a millionaire brewer at Milwaukee, who left \$500,000 for experiments in aerial navigation, one-fifth of it being specified as for Ritchel's machine. Ritchel will begin experiments on a large scale.

A MINER'S POCKET KNIFE.—A pocket knife has been patented by Mr. George Frenkel, of Durango, Col., designed for miners' use, to facilitate the cutting and capping of a fuse. The knife has a notch in the handle case and one in the blade, the latter having a screw thread formed on its bottom to press a screw thread on the end of a fuse placed in the notch of the handle.

EXTRACT OF LEMON is prepared by exposing four ounces of the exterior rind of lemons in the air until partially dry; then bruise in a Wedgwood mortar, and add to it two quarts alcohol, and agitate until the color is extracted; then add six ounces sweet oil of lemon. If it does not become clear immediately, let it stand for a day or two, agitating occasionally. Then filter.

ARTIFICIAL MARBLE can be made by soaking plaster of Paris in a solution of alum; bake it in an oven, and then grind it to a powder. In using mix it with water, and to produce the clouds and veins stir in any dry color you wish. This will become very hard and susceptible of a high polish.

EXTRACT OF VANILLA is prepared by cutting one ounce vanilla into small pieces, and triturate with two ounces sugar to a coarse powder; put it into a percolator, pour on it diluted alcohol until one pint has run through, then mix with one pint syrup.

GOOD HEALTH.

Diphtheria Caused by Overcrowding.

Dr. J. T. Hutton, a medical practitioner in Minnesota, has had large experience in cases of diphtheria, and has made that disease a special study. He says in the *Medical Record*, that his observation has convinced him that the principal cause of this disease is overcrowding in families or neighborhoods. He summarizes as follows:

1. Diphtheria is caused by ochlesia, or crowd poison.
2. It is an emergency—"an event or combination of circumstances which calls for immediate action or remedy."
3. It is at first a local disease, resembling the animal poisons—snake bite, mad dog bite. Properly treated in this stage, it is one of the most curable of diseases.
4. It is contagious and infectious, and the poison may retain its vitality from three months to two years.
5. This poison is not identical with that of measles, croup or scarlet fever, nor is it intimately related to them.
6. Diphtheria may occur sporadically; any small overcrowded, ill-ventilated house may prove a diphtheria factory.
7. Its period of incubation is from twelve hours to several days.
8. Directly, temperature none; indirectly much. Crowding can occur in any temperature; practically it occurs most in cold weather.
9. In the local stage there is but one indication—to destroy the false membrane already formed; prevent further formation and spread. For this only two remedies are required as a rule.
10. In the stage of systemic infection there are two indications—the foregoing, and to support the system. A remedy or combination, internally, with food and stimulants meets this indication.
11. An abundance of pure air is the first requisite in treatment.
12. Being an asthenic disorder and prone to heart failure, rest in the recumbent position and warmth to the extremities assist in the cure.
13. The physicians must not only prescribe, he must administer the local treatment, when present and see to it that food and medicine are administered punctually in his absence.
14. The physician should visit severe cases three times a day; all cases at least once a day for the first nine days.
15. The physician should not despair, though called late. I have seen patients, apparently moribund, restored by fresh air and food alone. So have other observers.

In the septic or putrifactive stage the diphtheria patient can hardly be overfed or overstimulated. Many die for want of food and stimulants to tide them over, the popular notion being that sick people do not require food, especially those who manifest febrile

action. Two quarts of milk, each pint holding a fresh egg in solution, one cupful of home-made beef essence, properly seasoned, a pint of pure port wine, or half that quantity of pure brandy, form a fair skeleton of one day's rations for an adult. Food and stimulants are administered every hour.

Alcohol and the Heart Beats.

As a rule, it is well to let the processes of life in our bodies go on without noticing it, for doubtless it would make us very nervous to have the internal machinery in motion before our eyes. But to prevent people from abusing that delicate machinery, it often becomes necessary to show it; and if a person addicted to wrong indulgence is made "nervous" by the sight, it may save him from being made something far worse.

Dr. N. B. Richardson, of London, the noted physician, says he was recently able to convey a considerable amount of conviction to an intelligent scholar, by a simple experiment. The scholar was singing the praises of the "Ruddy Bumper," and saying he could not get through the day without it, when Dr. Richardson said to him:

"Will you be good enough to feel my pulse as I stand here?"

He did so. I said, "Count it carefully; what does it say?"

"Your pulse says seventy-four."

I then sat down in a chair and asked him to count it again. He did so, and said, "Your pulse has gone down to seventy."

I then lay down on the lounge, and said:

"Will you take it again?"

He replied, "Why, it is only sixty-four; what an extraordinary thing!"

I then said, "When you lie down at night, that is the way nature gives your heart rest. You know nothing about it, but that beating organ is resting to that extent; and if you reckon it up, it is a great deal of rest, because in lying down the heart is doing ten strokes less a minute. Multiply that by 60 and it is 600; multiply it by 8 hours, and within a fraction it is 5,000 strokes different; and as the heart is throwing 6 ounces of blood at every stroke, it makes a difference of 30,000 ounces of lifting during the night."

"When I lie down at night without any alcohol—that is the rest my heart gets. But when you take your wine or grog you do not allow that rest, for the influence of alcohol is to increase the number of strokes, and instead of getting this rest you put on something like 15,000 extra strokes, and the result is you rise up very seedy and unfit for the next day's work till you have taken a little more of the 'ruddy bumper' which you say is the soul of man below."

Fluids and Fat.

The removal of surplus fat from the body by appropriate means naturally forms a subject of interest to the well-to-do classes. Various modifications of solid diet having had their day, the consumption of fluids is now undergoing regulation in respect of quantity among those who find their own presence insupportable. There is something in this theory, inasmuch as liquids, merely as such, materially aid the digestion and absorption of the food with which they are taken. Again, several of the fluids in most common use are, directly or indirectly, fat forming. Thus, cocoa contains a very large proportion of fat, coffee a considerable amount along with amyloid substances, which are also represented in tea to a much smaller extent, and which readily pass by chemical decomposition into the form of fat. Beer, wine and spirit are all fattening, partly in consequence of their saccharine and starchy constituents, and partly from their tendency to hinder excretion of waste products of food, and, when acting on any but a languid frame, to hurry and to slur that methodical oxidation by the blood on which the maintenance of sound tissue depends. General opinion, we are sure, will bear us out in saying that when the solids consumed are moderate in amount and digestible, and when the fluid is merely fluid, not fatty or amyloid in its composition, and not stimulant, free drinking will not influence obesity. We can call to mind heavy drinkers of water and regular consumers of tea, moderate in diet otherwise, whose habits engendered not the slightest tendency to corpulence. We should, without hesitation, recommend their practice to the stout, and should rely for the reduction of their bulk not on any further alteration of their diet, which might easily be carried so far as to starve their more important tissues, but on the maintenance of regular and sufficient physical exercise.—*Lancet*.

A HAIR RESTORER.—One drachm of carbolic acid, six drops of oil of lavender, and two and a half ounces of olive oil, formed the prescription which proved effectual in destroying a parasitic affection of the mustache of a gentleman who consulted Dr. Geo. Thew, of London, England. The hair had fallen out in spots, but after the application of the above remedy the hair grew as thick and healthy as before the parasite had attacked it.

COW'S MILK FOR CHILDREN.—Dr. V. Poullain believes that the reason that cow's milk so often disagrees with children is to be found in the fact that cane sugar is used to sweeten it. He says that for thirty-three years he has used the sugar of milk with the best possible results.

MINING SUMMARY.

The following is mostly condensed from journals published in the interior, in proximity to the mines mentioned.

CALIFORNIA.

Amador.

MISCELLANEOUS.—*Ledger*, June 21: The South Spring Hill continues to move along prosperously. The present run is expected to prove the richest yet made. The ore chute is said to be opened 180 ft, and the end is not yet; probably it will extend as much further into the ground yet unprospected. The mine is recognized on all sides as a permanent one. The Gover has not been started up yet, the cause of delay we have not heard. It is gratifying to be able to state the prospects of the Amador Consolidated of Sutter creek are improving. The rock is of better grade, and should the improvements continue, a new mill will be erected ere long. We are informed that a chunk of gold worth several hundred dollars was recently picked off the dump of the big tunnel at Middle Bar. It has been thrown out by the workman as useless. This discovery is important, showing that the rich ore streaks which have made that region famous penetrate far below any shaft yet sunk. It is reported that the Bright quartz claim just outside of the town limits of Jackson, is to be started up at once.

CHEROKEE ITEMS.—North San Juan *Times*, June 21: The North Bloomfield Company are drifting in their claims (at Malakoff). The Milton Mining Co., through their agents, have been taking a glance at the lay of their ground situated near Badger Hill, for the purpose of ascertaining whether or not it will pay for working by the drifting process. All large powers move slowly, hence we presume this company will make further investigations ere they commence operations. It is said by those who are good judges that the ground will pay by the drifting process of mining, and that a prospecting run will determine the fact. In the event of the Milton Company deciding to make such a test, a boom will commence in our neighborhood that will eclipse any quartz strike that has been made here for months.

Calaveras.

WEST POINT.—Cor. Calaveras *Chronicle*, June 21: Our interests in the upper country at present consist in quartz mining, milling, and the different methods of extracting gold from its native state to a state of activity. Our resources in that respect are abundant, especially the gold bearing quartz, the ledges of which range through our hills for a distance of eight square miles, all of which, though not what may be termed large, are good enough and large enough to pay, in most cases, good dividends to their owners if properly worked. Our gravel mines are all idle, untouched as yet by the prospector or capitalist. There is one old river bed alone, which at present is covered with lava, that can be traced for 20 miles along its course by its output in gold at different points. Several fine specimens have already been found, varying from \$5 to \$50 in weight, and were nearly all smooth, proving that they came from an "old wash" thousands of years past. I expect, in course of time, that this channel alone will furnish millions in gold to our future capitalists.

MINING NOTES.—At intervals I will give a brief location, history and description of the different noted mines in the West Point Mining district, which may be of interest to a great many outside of the ring of a quartz mill. The Scorpion mine is about one mile from the village of West Point. The mine has three working shafts down on the lode, at a distance of 150 ft from each other. No. 1 shaft is down 50 ft, showing a ledge 4 ft wide which prospects \$14 per ton. No. 2 shaft is down 110 ft, showing a ledge 2½ ft wide which prospects \$30 per ton. No. 3 shaft is down about 90 ft, showing a 2½ foot ledge which prospects \$100 per ton. A level has been started at a depth of 90 ft both ways in the No. 2 shaft, showing a splendid vein of good quartz all along. The quartz is impregnated with sometimes solid sulphurets and hard to work by the free milling process, but which can easily be made harmless and the gold extracted from it by the Russell process. The Co. are now engaged in erecting furnaces and mills in this district for all base sulphureted quartz, which, if successful, will exceed our greatest expectations in the near future.

Inyo.

THE MAXIM.—Inyo *Independent*, June 20: After a run of eight or ten days the new five-stamp mill of the Maxim Company, at Crysopolis, has hung up its stamps for a short time. We are not at liberty to state the exact result of working of ores of the arastra and the Hope mines, upon which the company has been operating, but may generalize it by giving the fact that two chunks of fine gold, weighing respectively two and six pounds have been shipped. Supt. Barrie started for New York Thursday, bent on matters pertaining to the erection of larger reduction works. A force of 15 miners is at work day and night exploiting the mines and getting out ore for the next run, which will commence immediately after the mill boys get through their well-earned rest and fourth of July.

A HANDSOME BUTTON OF BULLION.—Supt. Barrie brought in a handsome button of gold bullion from the Maxim mill Thursday morning, and took it to New York with him. He left on Thursday night stage to catch the Carson bound train and goes direct to New York, and will probably be gone about three weeks.

PINE MOUNTAIN.—S. P. Roberts was in from Pine Mountain last Monday. He thinks it will yet prove to be the best mining section in Inyo county. Mr. Roberts has several tons of ore ready for shipment to some furnaces. He showed us some assays from ores at that point that went very high.

Mono.

MAY LUNDY.—Homer Mining *Index*, June 23: The May Lundy mill has been running the full ten stamps all this week, and the machinery is in excellent condition. The mill is now run entirely by water, of which there is a great surplus. Carpenters are engaged in preparing the foundation for the additional battery of five stamps. At the mine, No. 3 (lower) tunnel is being steadily advanced, in fine ore, to make room for additional stopes when needed, though for the present the old workings afford an abundant supply. Clearings are also being made for

other contemplated new work, and the mine is being opened up on a much more comprehensive scale than heretofore. The Lake View (first south extension, and same owners) is also being cleared for action, and will probably be running full handed by the end of next week. It is being opened on a transverse ridge just south of the point where many tons of high grade ore was taken from the croppings last year, the latter point being a sag where the workmen would now be in danger of interment by slides from overhanging banks of snow. A snow slide took away over 100 ft of the tramway on Tuesday last, but it was replaced and in running order next day at noon, so that practically no interruption occurred to mine, ore teams or mill. The Bryant is working as many men as the present openings will accommodate, and the pack trail from the mine down to the wagon road has been put in order for transportation of ore. Both the north and south drifts on the 130 level are in ore of high grade—some of it being extremely rich in free gold, and the entire mass being of a higher average than the ore of any other mine yet opened in the district. They will probably put on a pack train and start up the Butterfield mill next week. Work at the Gorilla mine has been retarded by snow slides occurring during the week. The upper section of the tramway was partially reburyed by one end of these slides, but not otherwise injured, and it was expected that everything would be in readiness to put a full force of men in the mine today. The new Planet mill is in place at the company's reduction works, and will probably be put on trial to-day. There is a strong probability that an extensive group of claims in this district has been sold to European capitalists, and that the new company's manager will arrive here early next week to make arrangements for starting up work. The Great Sierra tunnel, Tioga district, is still making rapid progress, and will doubtless reach the Sheepherder vein before the end of the month. The Virginia creek hydraulic is running full handed and with all the water that can be utilized.

BODIE CON.—Bodie *Free Press*, June 23: Five hundred and forty-six tons of ore were crushed at the mill during the past week. The average assay of the pulp was \$33 15, and of the tailings, \$2 75. There is no change in the ore breasts to report. South drift from winze No. 2, Vulcan vein, 306-foot level, is in 45 ft.

STANDARD CON.—There was extracted and shipped to the mill 600 tons of ore, the amalgam from which is not yet retorted. South drift No. 1, from south winze No. 2, 385-foot level, has been extended 10 ft; total length, 105 ft. The vein is about 2 ft wide. North drift No. 3, from main west crosscut is in 194 ft, 11 ft showing 3 ft of ore vein.

BULWER CON.—The south drift from the west crosscut No. 2, 500-foot level, has been extended during the week 12 ft; total length, 296 ft. The vein is about 1½ ft wide.

BODIE TUNNEL.—Advanced 16 ft on the vein in north drift, on the 200-foot level.

Modoc.

SHUT DOWN.—Cor. Adin *Argus*: The recent rains have retarded progress at Hayden hill in milling ore. Most of the mills and arastras have been compelled to shut down until the roads settle enough to enable teams to haul ore. Preston & Co. will soon have their new arastra completed and ready for work.

Nevada.

NOTES.—*Transcript*, June 21: The new hoisting and pumping works at the Little Deer creek mine are about completed, and the machinery will be started next Monday. This quartz claim has within a short time come to the front as one of the best in the district for the amount of work done. The Nevada drift mine at You Bet has about 50 men on the pay-roll and is proving profitable to the owners, the South Yuba Water and Mining Company. The Nevada was formerly worked by the hydraulic process, and although it doubtless yielded larger dividends than now, not more than half the number of men ever found work there than now do. The gravel is cemented and has to be crushed in a stamp mill the same as is done with quartz.

A GOOD INVESTMENT.—The owners of a quartz mine in this district, who recently paid between three and four thousand dollars for the property, are said to have since been offered \$20,000 for it and have refused to consider the offer. The mine referred to is one that has not until recently been heard from, but from present indications it will turn out a good deal of gold during the next few years.

RICH STRIKE.—*Herald*, June 17: A streak of very rich quartz was struck in the Merrifield mine yesterday. The rock is heavily charged with rich-looking sulphurets and shows well in free gold. A fine specimen of the ore was on exhibition at the Citizens Bank to-day. The main ledge is from two to three ft in width, but the rich streak of quartz is about 10 inches wide. We are pleased to learn of this development and hope the strike will prove to be extensive. Since Supt. Hughes took charge of the Merrifield he has worked hard to open it up, and this discovery is very gratifying to his friends as well as to himself.

LITTLE DEER CREEK MINE.—*Herald*, June 20: We learn that Marsh & Hothersall, owners of the above named quartz mine, which is situated on Little Deer creek, near Canada Hill, have refused an offer of \$20,000 for their property. A shaft has been sunk about 50 ft, and at the bottom there is a splendid ledge of quartz that averages 18 inches in width. The rock shows well in sulphurets and free gold and there is every indication that a rich mine will be developed. Hoisting works, run by a Pelton water wheel, have been erected, and the owners feel very sanguine over their prospects. A six-inch pump has just been put in. Some very rich rock was taken from this same mine years ago, but no systematic work was ever done on it.

ANOTHER RICH FIND.—*Tidings*, June 20: We learn that indefatigable Reese, who lives on Randolph Flat, has again made one of his semi-occasional rich finds. For a number of years Mr. Reese has been prospecting on Dead Man's Flat, and has on several occasions made strikes of from \$2,000 to \$10,000 by following some of the numerous stringers of quartz that abound in that famous region. Several days since Mr. Reese made a strike on one of those stringers, and from one panful of decomposed rock he washed out \$100, several panfuls each paid \$10, \$15 and \$5. The only trouble

about this is that it is not far enough away from Grass Valley to get up a boom.

Plumas.

ELIZABETHTOWN.—*Plumas National*, June 21: The Loring & Leavitt shaft is down about 100 ft, and a drift will now be pushed to the east to open the channel. The shaft is as true as a die, and solid from top to bottom. The water has not bothered them to any extent. Bedrock was struck at the depth of 78 ft. The channel is evidently to the east of them, and a very short time will show it up. Loring & Leavitt have good prospects, and they certainly deserve good pay as they are energetic and hard-working men.

FINE QUARTZ.—Mr. Jos. Hallsted, who came up from Rich gulch on Saturday brought us some specimens which will compare well with the best rock on exhibition in the cabinet. There is no doubt but that the Hallsted mine is one of the best quartz mines in Northern California, and it will prove so at no distant day. We expect to take a trip down that way before long, and will then be able to give a full description.

Sierra.

PUMPING OUT WATER.—*Sierra Tribune*, June 21: Work is progressing finely at the Marguerite mine, Loganville. The shaft has been cleared of water to the third level. About 30 men are employed at present and the force is being constantly increased. Operations on the new shaft will begin soon.

Siskiyou.

PICK AND PAN.—*Yreka Union*, June 25: Considerable excitement is prevailing in Quartz Valley over the rich strike in quartz made by George Tonkins in his lead near Mugginsville, which, rumor says, will pay \$200 per ton. Mr. Tonkins has hammered out with a hand mortar at odd times something like \$16 in the past two weeks, merely testing it. Quite a number of prospectors are investigating Oro Fino mountain this week, among who are Charley Birnbaum and Robert Small. John Miller & Company, near Hawkinsville, have cleaned up their diggings for the present by the use of free water from their Greenhorn ditch, and we are informed have divided a good dividend among the shareholders. They expect to commence work again as soon as the water reaches them through the big ditch. Wm. Booth has quite a piece of ground stripped and is ready for washing pay dirt when water reaches his valuable claim. Kittlewood and company on the Klamath, below the mouth of Scott river, have several cribs in and will soon be ready to go to work. Mapleson, below the mouth of Scott river, has secured all the material necessary for the construction of wing dams and is getting ready to put them in. Mr. Dan Caldwell informs us that the miners around Hamburg Bar are all at work, most of them doing well. On his trip up the river he observed a number putting in cribs, among them Barton and company, Jackson and several others. Work ground has been worked in the Montezuma mine at Callaghans already this season, under the management of James B. Parker, than was moved in the entire season last year. The result will be attended with success. The Campbell hydraulic mine at Quartz Valley is being worked at its greatest capacity, 25 or 30 men being employed. All practical miners predict a big clean up for Mr. Campbell, and his enterprise certainly deserves it. He has done more for his country during his short residence, than many who have been here a life-time. Lincoln and company on McAdams creek took out 112 ounces of gold in their claim in 24 hours last week. Mucker, Behne and Knight are running their arastra day and night, and crush about 60 tons a month. The Centennial Company on the Klamath are working 14 men and will put on a night force as soon as they reach the good pay which will occur in a few weeks. The Fort Jones Co. are working night and day and Sundays on the Klamath and will do well this season.

MINING NOTES.—Cor. Yreka *Union*, June 20: Work on the mine of Camp. Bailey & Woods is suspended for want of water. Other hydraulic claims on the Klamath, in Sciad valley are idle for the same reason. Mr. Martin Andrews, who has been for some time engaged in preparing machinery to open his mine, will soon be ready to go to work. The Grizzly mine on Indian creek has furnished some rich rock this year, which the company has crushed in their new stamp-mill. They had not cleaned up when I passed through last Sunday. Mr. Ed. Brown is also interested in a quartz lead on French creek which, he informs us, pays \$40 per ton. If this rich pay continues he will reap an abundant harvest. Six new arastras are being erected in and around Deadwood, over the Greenhorn divide, owing to the opening of new mines and the better prospect of old ones.

Tuolumne.

SOULSBYVILLE.—*Tuolumne Independent*, June 21: They are crushing rock in the Morris mill at Soulsbyville, from the live Oak. This is said to be good property, but little work has been done for several years. Some quartz speculators took a look at the B. O. mine, at Soulsbyville, this week, and then went across the river to look at another mine.

NEVADA.

Washoe District.

MEXICAN.—*Enterprise*, June 21: Are engaged in cutting out for a pump tank at the 3200 level. This tank will be completed and sinking resumed the first of next week. The winze will be sunk to the 3300 level as rapidly as possible, and will reach that point in eight or ten weeks. It is necessary to put in a pump tank at the 3200 level, as 200 ft is too great a distance to pump to advantage at one lift. Thus far very little water has been encountered in sinking the winze.

COMBINATION SHAFT.—The work of cutting out the station at the 2900 level and preparing for placing in position the big Cornish pump is being pushed to completion as rapidly as possible. The pump will be ready to start up about the time that the bulkhead on the 2600 level of the Chollar is completed. With the Cornish pump in operation at the 2900 level, there will be no danger in pushing exploring drifts on the level above.

BEST AND BELCHER.—The joint Gould and Curry west drift on the 2500 level is being advanced at the rate of 20 ft per week, though the rock is exceedingly hard. Owing to the heavy expenses incurred in combating the water on the 2700 level, it was deemed advisable to suspend operations until such time as the water shows signs of decreasing. They

can resume at any time, as the pumps will be kept running.

CON. VIRGINIA.—The east drift on the 2900 level has been advanced about 30 ft. Have completed repairing the C. and C. joint shaft. Have also completed a cooling-off house for the use of the miners working in the heated drift, and now have everything in good shape for withstanding the heat incident to the hot weather on the surface.

HAILE AND NORCROSS.—About 1,000 tons of ore from the deposit on the 200 level have been shipped to the Mexican mill, on the Carson river, where it is being worked. Returns from this ore will be received in a day or two. They will undoubtedly be good. Work has not yet been resumed on the 2800 level in the prospecting drifts.

ALTA.—Are pushing forward the west drift on the 2150 level as rapidly as possible. It is following the course of the diamond drill hole. This drift will settle the question of the value of the country to the west.

GOULD AND CURRY.—Good headway is making in the two crosscuts that are being run to the east on the 1200 level. The material is in a favorable formation, consisting of a mixture of quartz, clay and porphyry.

IMPERIAL.—The lateral drift from the main west drift is in Alpha ground. It shows much quartz of a favorable appearance, and the indications are good for finding ore that will pay a profit for milling.

YELLOW JACKET.—Sufficient ore is being extracted to keep the mills on the Carson river in constant operation. The exploring drifts are finding a considerable amount of ore that will pay for milling.

CROWN POINT.—Sufficient ore is being extracted to keep the mills on the Carson river in operation to their full capacity, and a considerable amount of work in the way of exploration is being done.

BELCHER.—Enough ore is being taken out to keep the mills on the Carson river in full blast, and a considerable amount of ore is being opened out ahead by the exploring drifts.

SAVAGE.—Prospecting work has not yet been resumed. The new bulkhead on the 2700 level has proved a success in every respect. Not a drop of water passes it.

ANDES.—Some paying ore is being found, and the prospecting drifts show a great deal of quartz of a favorable appearance.

CHOLLAR.—Good headway is making in the work of putting in the stone bulkhead on the 2600 level.

UNION SHAFT.—Are still repairing the drain drift on the 1600 level leading out to the Sutro tunnel.

Bristol District.

A SUCCESS.—The draft furnace test, recently made by the inventor, Mr. Bassett, at Bristol, has proven successful, so far. The other day he ran a lot of ore, from the Terror mine, owned by Dan Roeder, through the little furnace. This ore went \$62 85 in silver and 50½ per cent lead. The ore run through the furnace freely and ten bars of bullion, weighing 548 pounds, and going \$141 35 in silver, was the result. There are to be made several improvements on the furnace, after being thoroughly tested, proves a success, then all the 530 -uniting ore in this country will be worked with big profit.

The furnace turned out for the month of May 85 tons of bullion. The "Gipsy," owned by Henry Deno, is developing into a handsome property, the ore body becoming stronger and rich as depth is attained.

Columbus District.

MOUNT DIABLO.—*True Fissure*, June 21: The west intermediate drift from winze No. 5 is in 61 ft, and shows some good ore in the face. The east intermediate from the same winze shows a little ore. A drift is being driven east on some ore on the third level west of the shaft, and there is a strong ledge showing, with some good ore. The west intermediate, between the second and third levels, is in 71 ft, and shows some 2 ft of \$35 ore. The raise from the south crosscut, on the second level, is up 80 ft, and shows a little ore. The east drift from the north crosscut, on the second level, shows some 6 inches of \$75 ore. In the intermediate, between the first and second levels, the west drift is in 51 ft, and shows some \$60 quartz. The north crosscut from the west drift on the third level has been stopped; total length, 87 ft. A drift has been started on a small streak of ore cut by this crosscut. The raise from the east drift on the first level shows some \$60 ore. The station has been cut out in the incline, and sinking has been resumed. The east drift from the incline, which is to connect with winze No. 3, is in 14 ft.

Cottonwood District.

NICKEL.—Lookout is alive with mining experts, bound for the nickel and cobalt mines of Cottonwood. There are some 13 in all of these experts, most of them from the East. The hotels, livery stables and saloons are doing a good business, and considerable of the "ardent" is punished under the guise of lemonade. The mining excitement is running high, and it seems as if the long expected boom is at hand.

Eureka District.

EUREKA TUNNEL MINE.—*Sentinel*, June 20: The company are employing a force of 15 men, including the contractors at work in the shaft, which is being sunk below the 200 level from the tunnel, and will be continued to a further depth of 100 ft, at which point a station will be opened, and from which a drift will be run westerly to cut a vein of ore appearing in the shaft 10 ft below the 200 level. On the 200 level a drift is being run in an easterly direction, for the purpose of prospecting under the old ore chambers, and it already shows in spots and seams, ore of the same character and richness as that heretofore obtained in the ground above. One seam in particular stands almost vertically in the drift. The ore it carries is a fine quality of quartz, and although small at present, gives promise of more strength and thickness as followed downwards. To favor the belief in larger developments in this locality, there appears in the bottom of the drift a quantity of black oxide of manganese, carrying yellow chloride, the exact counterpart of that which characterized the ore body first discovered in the winze from the south drift from the tunnel level. This was traced downwards 150 ft, and the present discovery on the 200 level shows a continuation of the same to this depth, from where it may open out in ample proportions similar to the stopes above. The ore

seam in the shaft at a point 10 ft below the 200 level is worthy of particular mention. Its character is a yellowish carbonate, rather heavy with lead, and different from any ore previously discovered in the mine. Tests assays show that it carries over 100 ounces of silver and about 30 per cent of lead. It dips northwesterly, and its course will be crossed by the drift to be run from the 300 level. The latter point will be 800 ft from the surface, and at this depth the proprietors hope for and expect to develop ore bodies in Prospect mountain in a more compact form than those that are being continually discovered nearer to the grass roots, and there is no reason why these ore bodies should not prove to be as extensive as those of Ruby Hill. In the crosscut from the south drift, 200 level, is a small seam of ore taking its course southwesterly, on which a prospecting drift will soon be run. There are six men employed following ore from the old chambers, the yield from which contributes largely towards the payment of the expenses of prospecting the mine, which, by its new organization, is entirely freed from debt.

Mount Hope District

PROMISING.—*Cor. Eureka Sentinel*, June 20: It may be of interest to many of your readers to know where Mount Hope district is situated. It is twenty-five miles north from Eureka, on the line of the E. & P. R. R., one mile west from the road. It was formerly known as McGarry district, and like many others, it was abandoned for want of practical knowledge and the necessary development of its mineral deposits. Some years ago Hon. Thomas Wren's attention was called to this now promising and important mining region. He set men to work to prospect it. Your scribe last Sunday paid a visit to Mount Hope, and he was agreeably surprised to find there such a showing. The development is as great as any I know of that has ever been found in this country for the same amount of work done. At a depth of only 20 ft a solid mass of galena and carbonate ore is uncovered. Its extent is great, but cannot yet be accurately calculated, but it looks big. The surface shows mineral for 800 ft east and west and one mile north and south, with a mountain of porphyry for the hanging wall and quartz and lime for the foot wall. The find will average \$35 per ton, the ore averaging 35 per cent lead. The ore can be shipped to Eureka at a cost not exceeding \$2 50 per ton, and in time for \$1 50 per ton. I saw a breast-hole blasted yesterday that threw out one and a half tons, of which I leave you a sample. [Of very fine-looking galena.]—*Ed. Sentinel*. Mount Hope is a continuation of Ruby Hill, and Prospect mountain to the north. Mr. Wren deserves success for his pluck and energy in trying to find a mine. He has spent a fortune in prospecting, and he has never yet refused to help any worthy prospector.

Patterson District

ORE.—*Pioche Record*, June 21: Mr. Flower from Patterson district had some very rich ore tested lately by Mr. Kelsey, assayer for the Day Mining Company. The ore averages 107 ounces per ton. One sample went \$2,694. The old gentleman claims to have several hundreds tons of lulling ore that will average \$64 per ton.

Pennsylvania District

START UP.—*Pioche Record*, June 21: In all probability work will be started up in this district soon. Geo. Rives and McGrath arrived from Eureka on Thursday afternoon, and we learn from Louis Sultan that a satisfactory agreement will be made by all owners in the mining property.

Pioche District

WILL BE AT WORK.—*Pioche Record*, June 21: The works at Bullionville will most likely be going in less than two months. Fred Godbe has made contract for wood. The tailings are to be first roasted and then leached. All the tests having been made by this process have proven very satisfactory. Mr. W. S. Godbe is expected to arrive at Bullionville in about a week. The starting up of these works will be a Godsend to the Panicans.

Silverado District

CONCENTRATING ORES AT PINTO.—*Eureka Sentinel*, June 23: John Tregonning is concentrating ore from the Rescue mine, Silverado, at the Pinto Mill. He is making a trial of a process by which he thinks any quantity of lead ores can be made profitable. He is experimenting with a lot of 25 tons, and has so far been quite successful.

Tuscarora District

NORTH BELLE ISLE.—*Times-Review*, June 20: No. 2 crosscut, 350-foot level, has been extended a total distance of 24½ ft. Drift north, on the 70-foot level, has been advanced 10 ft.

BELLE ISLE.—Crosscut on the 450-foot level has been extended 10 ft; total length, 137½ ft. Work will be resumed in a few days in the joint Belle Isle and Navajo upraise on the "east" vein, 250-foot level.

GRAND PRIZE.—South drift on the 200-foot level advanced 39 ft. South drift on the 300-foot level advanced 37 ft. South drift on the 400-foot level advanced 22 ft. All other work progressing favorably.

INDEPENDENCE.—Fair progress has been made in extending drift north on the 400-foot level. Favorable formation continues, and a strong seam of ore was cut during the past week. Upraise from the 300-foot level was carried up 26 ft; total height, 77½ ft. There is no material change to note in the other workings.

ARIZONA.

THE SITUATION.—Prescott *Courier*, June 20: The mining situation in this county is about as follows: United Verde company continues to take out and ship copper-silver bullion by the wagon load. Their great mines look as if they never would give out. Coke is accumulating at the smelter and the company propose to be ready for a rainy day or days. The Conger property, in Cherry creek district, will soon be sending forth bullion. The company has a good mine and mill. A mill is going up in Humburg district, and many miners are employed there. A 10 stamp mill is being erected at the Kimball mine. Mr. Eaman has a large supply of Lane ore at the Black Warrior mill. Bradshaw and Turkey creek district miners have plenty of rich ore raised, but we hear of no crushing or smelting. The last shipment of 103 tons of Dosoris ore to Pueblo, netted the company several thousand dollars. Dosoris company own the Buzzard and Raven mine,

which has a big wall of rich silver ore in it. The Dosoris, Blue Dick and Mark Twain mines are given good characters by miners who have no interest in them. A mill is being fitted up on Upper Lynx creek. Mr. Clark is pumping water out of the Chicago mine, Groom creek district, and will very soon start his mill. The foregoing are about all the active enterprises we can now bring to mind. We wish there were more to chronicle. The showing does small justice to this section of Arizona, where there are, we firmly believe, scores of mines which carry ores rich enough to pay for mining and for almost any sort of decent treatment. As we have often before stated, only the richest ores will bear cost of transportation, etc., out of the territory, and it does strike our people, forcibly, that the era of big mining will not come until after the advent of the railroad.

MINING IN MOHAVE.—*Miner*, June 21: Miners in the vicinity of Stockton hill who have taken their ore to the Hackberry mill, have expressed themselves well satisfied with their treatment. J. Gail, who recently purchased the Moonbeam mine of P. Hach and Ed. Burke, took three tons of ore to the Hackberry mill, from which he realized over \$1,000. Mr. Foreman, of the Pueblo smelting works, is still in Kingman, and has several carloads of ore already piled up on the platform at the depot ready for shipment to his company as soon as the road is repaired. He informs us that his company has recently added three forty-ton galena furnaces to their capacity, and that the company want 20 tons of lead ore per day more than heretofore. Tiburcio Padilla brought up a sack of ore from his new strike in Cedar district, and had it sampled at the Kingman sampling works. It assayed at the rate of 224 ounces in gold, or \$4,480 per ton. Tiburcio says the sack full he brought up was from the surface croppings, and that he has plenty more of the same kind.

COLORADO.

MINING NOTES.—*Colorado Mining Gazette*, June 20: A force of 10 men is working on the Eclipse mine, Cascade mining district. Another body of high-grade ore has been struck in the Gold Leaf mine, Soda creek. The Silver Plume mill has closed down for repairs. New machinery is to be added. John M. Dumont, Esq., purchased the Ninth mine, near Empire, last week, paying \$60,000 for it. W. P. Ferris & Co. had a run of 21 tons of Joe Reynolds ore this week, which netted \$4,917. Mr. Charles Thompson, who is leasing on the Thunderbolt lode, Ute creek, is extracting good ore that pays well. The mining outlook has never been as favorable as at present for Idaho Springs. It has been an agreeable surprise to our energetic mill men. There is a great deal of prospecting being done in Gold Dirt mining district. Quite a number of location surveys have been made the past week. Seven hundred feet of six-inch air pipe has been placed in the Foxhall tunnel this week. They are now working day and night on this enterprise. Work was started up this week on the main working shaft of the Saratoga mine, Russell district. It is reported that prospecting by deep sinking will be the object of the management.

IDAHO.

THE COLORADO CON. PLACER.—*Coeur d'Alene Eagle*, June 20: Work on this valuable property has been delayed by continued high water, caused by the mountain storms which have prevailed during the week and which swelled the creek to a point where work cannot be done to good advantage. On Tuesday a force of men started in to sink to the bed of the old channel, the rim of which is exposed for a distance of several ft. A pump has been put in which does good work and the men are sinking through a gravel that pans out some famous prospects. Offers have been made by responsible parties to run a timbered drift for 300 ft for no other pay than the privilege of washing the dirt extracted. The proprietors, Messrs. Curry, Baker, Lee and Parker, are delighted with the prospects in sight.

EAGLE DISTRICT.—Nothing speaks more favorably for the growth of a mining camp, than its division into districts. Originally Coeur d'Alene district embraced all of Shoshone county, except the Pierce district. The next district to be organized was Summit, then Beaver then Evolution and now Eagle district steps forward with another organization. In each of these districts good placer and quartz claims have been found, and each possess the elements to make lively little camps. None of the districts, however, have a really good set of district laws, hence the development of claims will be retarded a greater or less time, depending upon the enterprise of claim owners and their faith in the value of their ground. A more insane and senseless law, than the 20 acre placer claims, never lumbered the U. S. statutes, and while that disgusted monopoly remains a law, it is idle to look for practical development. Twenty acres of creek ground is too much for a placer claim. It is not a mining claim, but a ranch. We wish some retroactive law could be secured, that would give us a new deal all around.

ANOTHER MINE SOLD.—Last week a gentleman from Maine, named Snow, visited Dream gulch to see the Webfoot claim, and after seeing that famous elephant, went on up the creek to inspect the quartz ledges with which that gulch is seamed. Arriving at Frank Reed's Lucky Baldwin, he was so impressed with the character of the quartz and the formation, that he immediately bonked the mine for New York capitalists for \$10,000 paying also a handsome spot cash forfeit in case the dicker falls through. The Lucky Baldwin is a good mine and is worth every dollar of the bond.

THE CUSTER CO.—*Cor. Keystone*, June 20: The Custer mill, 30 stamps, has been running regularly, with a yield of \$40,000 to \$50,000 per month. The yield has not been much less on an average, than \$1,000,000 per year. The bullion is about one-third gold. A winze sank 60 ft below the floor of the lower tunnel of the Charles Dickens, with levels run east and west, give a showing of four or six feet of ore, with a high average. The higher grade is stored in the mine, and the lower grade is on the dump and in the ore houses, of which there are 5,000 or 8,000 tons. There are three veins in the Dickens location, and each of them rich. The mine is opened to a depth considerably over 300 ft. The Montana mine, on Mount Estes, had over 400 tons of ore worked in the Custer mill, the gross yield of which was \$98,000. There is considerable shipping ore out. This mine is

also over 300 ft deep, and good ore in the bottom, between 35 and 40 tons of ore from the Whale, sent to the Custer mill, sampled over \$400 per ton. To all appearance the Whale is one of the best locations in that section. The camp employs about 250 men, and the population of Bonanza and Custer, including the men about the mines, keeps at its usual standard—probably 350. Nearly all the Stanley Basin country was brought up last season by a Wood River and Nebraska company, and it is the intention to bring in a large ditch from the Basin and tributary creeks with which to work the extensive placers. There is a new quartz camp struck between Stanley and Cape Horn, and the ores so far assay well. On Loon creek there will be more done this season than for years past, both in placers and quartz. Several companies are at work there now.

ANOTHER STRIKE IN TENDERFEET.—*Wood River Times*, June 18: Gophers and "tenderfeet" have proved the best prospectors that this country has had, so far. This saying is rapidly acquiring the dignity of a truism, as events seem to justify it. Only a few weeks ago it was reported that two "tenderfeet" had struck an ore vein up Quigley gulch, at a point scarcely four miles from and in full view of Hailey. This report was well founded. The vein was struck April 12th, and since then has been uncovered in several places, and found to average four feet in width. The vein carries two streaks of pay ore, the best of which yields 146 ounces silver and 65 per cent lead; while the second grade carries 116 ounces silver, and 40 per cent lead. The vein lies between quartzite and lime, and is well defined. About eight tons of first-class ore on the dump will be hauled in as soon as the roads will permit.

THE MAYFLOWER ORE VEIN.—As has before been stated in this paper, the Mayflower Mining Co. have for nearly two years past, been looking for a continuation of their vein on the lower level, which, owing to a "fault" or displacement, had been lost. After running over 130 ft from the line of the old workings they reached ledge matter, and, day before yesterday, cut into an ore vein having precisely the same characteristics as the old vein, and being evidently a continuation of the same. This proves the continuity, in depth, of the main mineral belt of this country beyond any doubt, and it is, therefore, as good as demonstrated that this belt extends from the Minnie Moore to and beyond Bullion.

MAGGIE D.—Work on the Maggie D. placer, just above town, is being pushed as fast as enterprise can do it. The China pump has been doing good work, and the shaft has obtained a depth where another pump is necessary. The second pump was put in on Monday and it is now expected to reach bedrock very soon. The pump may be worked by hand, but a ditch 1,400 feet long will bring water from Pritchard creek with a head of ten feet, which, with an overshot water wheel, will furnish power to work the pump night and day. The pump thus takes the place of a bedrock drain. The shaft will be sunk to bedrock, upon which drifts will be run, and the property thoroughly developed. If it proves to be as valuable as expected, hoisting works will be erected by which the pay dirt will be hoisted to the sluice boxes, which will be abundantly supplied with water from the supply ditch after it has done service in turning the overshot wheel. At the start, considerable waste will have to be hoisted with the pay, but after a single drift has been worked out, it will furnish an underground waste dump, where may be stowed the rock and gravel which is easily separated from the pay dirt. The plan seems entirely feasible and is likely to furnish a solution to the difficulty of working our deep wash claims, which will result in the development of the entire lower gulch.

MONTANA.

ANACONDA.—*Cor. Butte Miner*, June 20: We have been three weeks making up our mind in regard to this camp, and the more we see and the more we reflect the greater is our wonder and surprise at the present state and future prospects of the year-old town. Leaving the busy camp with its ceaseless noise and hammer, saw and plane, and its litter of shavings, brick, mortar and lumber, we cross Warm Spring river, pass over a meadow-like green, shaded by fragrant balm of Gilead trees, and take a look at the new works. The buildings are simply immense. We try to imagine the scene when 28 furnaces are in full blast in the smelter building and the concentrating machinery is in motion. The preparations for active work are everywhere noticeable. The acres and acres of cord wood piled compactly in long rows make a sight to remember. Then there is the brick yard, and the lumber yard, and the stone walled tunnel leading from the works to the river.

The Alice is looking exceptionally well on the south vein and a heavy production continues; not much is being done on the main ledge. A report was current some time ago of a probable resumption of sinking in the main shaft to a depth of 1,000 ft, but work has not been completed yet despite the encouraging appearance and heavy productiveness of the south vein. The Magna Charta holds up in good shape and contributes its usual quota of ore to the mills. The Mountain View improves with every stroke of the pick and may prove the second copper mine of the district. Owing to the pluck, enterprise and brains of C. N. Larabee it has been opened to a depth of 500 ft and the only machinery used up to within two months ago was a second-hand whim and a bobtailed horse. It was the most primitive hoist ever employed to sink a shaft to that depth. Mr. Larabee is now taking out plenty of ore from the north and south veins and has enough ore in sight to justify the erection of a 100 ton smelter. The Liquidator is looking well and will soon be fully opened from the 300-foot station. The Lexington is looking well in all the levels, and the bullion which for some time has been quite base is now of satisfactory fineness, thus showing an improvement in the mill workings. The Company has on hand a surplus in the Paris office, from which Judge Davis, while in a confidential mood recently, told a reporter another dividend would soon be declared. The Poser is making a good record and shows plenty of ore in the lower level. The last lot shipped to the Silver Bow mill sampled 76 oz. The vein, however, will not sample that much. There is a report on the street to-day that operations are to be resumed on the Stevens soon. It is a good mine and ought to be worked. The Moulton is running along smoothly, and the 200, 300, 400 foot slopes are producing well. Another dividend may soon be ex-

pected. It will be an honest dividend, as the Company is out of debt.

THE LEADING PROSPECTS.—*Inter Mountain*, June 19: The shaft on Clark's Colusa is being rapidly sunk to the 300-foot station and is now 240 feet deep. In the east and west drifts from the 100-foot station, stoping is progressing, the output being from 25 to 30 tons of copper ore. The total length of the level is 175 ft. In the 200-ft level the stopes are also being worked both east and west of the shaft, the output being about 40 tons per day. The shipments in April were 700 tons, in May 400 tons and in June will approximate 500, which amount would be doubled if the sinking of the shaft did not retard operations. The shipping ore carries from 30 to 40 per cent copper. In addition to the ore shipped, about 12 tons a day have been sent to the Colorado smelter for the past three months for reduction into matte, and about 40 tons assaying from 12 to 18 per cent, have been extracted and dumped as third-class ore. To treat the vast quantity of low grade ore available for extraction, it is the purpose of the company to build a 60-ton concentrator, for which plans have already been drawn and accepted. Very little is heard of the Bell now-a-days, as the management is reticent and tries to keep very dark. It is a fact, however, that a bonanza has been found in the west 400 ft drift, and that the smelter is in very profitable operations. This will be denied but it is a fact, all the same. To use a homely phrase, the Bell smelter is making money "hand over fist," and is working daily from 25 to 30 tons of excellent copper ore, running high in silver. The Montana smelter is maintaining its splendid record. The company is so confident of the future of the mine that the management recently threatened to build a big refinery east if a contemplated pooling arrangement was perfected between European and Chilean producers, and to give the pool a lively deal.

NEW MEXICO

ORGAN NOTES.—*Cor. Rio Grande Republican*, June 21: The smelter will run on galena ore next week if the fuel holds out. Another car load of copper bullion was shipped from the Memphis. They have made another good strike in the Silver Gem, in a different part of the lead. The whole face of the drift in the 150-foot level in the Memphis is now said to be in good ore. Fourteen men are at work on the Silver Gem, ten or twelve of whom are doing development work and the others are stoping out ore for shipment. Work will again go on at the Little Buck next week. Ore will be delivered daily at the smelter, principally low grade, a considerable quantity of which is on the dumps. Our miners will now be encouraged to bring their ore in from the different prospects, for the smelter company will undoubtedly give for the ore all it is worth after sampling. The wagon load of ore brought in last week by McLoughlin and Mayberry from the Saratoga claim, in the San Andres, for a mill run, yielded 27½ per cent copper. And they claim to have a big body of it. Brown and Clark have again commenced work on the Black Prince. It is generally believed that this property can now be worked at a considerable profit, as they have shipped one car load to Colorado, which, after paying the enormous freight, left a sufficient margin to reimburse them for the labor expended, and a profit besides. The Poor Man's Friend, about three-quarters of a mile southeast of the Memphis, is a very promising claim belonging to Captain Richards and others. It has a thirty-foot tunnel running in, and four shafts on the vein averaging 18 ft each, all in ore. The vein is a good wide one, and the mineral is galena, chlorides and black sulphures, assays from which run from 14 to 120 ozs. silver.

OREGON.

NEWS.—*Jacksonville Times*, June 20: Considerable prospecting is being done in Jackson and Josephine counties. A successful run is being made at Wimer & Co.'s mine near Waldo. It is proposed to clean up there soon. Roten & Sons are taking some quartz from their ledge in Willow Springs precinct, which shows considerable free gold. John Rush of Evans creek has discovered a chrome deposit, which promises to be valuable, as it is extensive and evidently of good quality. The Sterling Company's ditch is still running a full head and two pipes are kept busy. The snow in the mountains is nearly gone, however. Cleaning up will be commenced before long.

UTAH.

PARK NOTES.—*Record*, June 21: The Ontario company is taking advantage of the present high water in the creek running down the canyon, to wash away the dump at the mine. Quite a large amount of prospecting is being done on the west side of Thayne's canyon. Prospectors have great faith in the future of that side. Roscamp and Glenn have made a new discovery in a claim called the Columbia. The vein is between a white silicious lime and quartzite and galena. The claim is near the Black Bear. The Bon Homme Co. have begun sinking a shaft on their property up the left hand fork of Thayne's canyon. This was made necessary by the foul air they encountered in the other workings. A contract has been let to Mr. Wm. Connor, to drive a tunnel 250 ft on the Crystal Mine, in the Big Cottonwood district. This property is owned by Salt Lake parties. Mr. Connor will start work on his contract as soon as he can get over in that part of the country with supplies. The Pioche *Record*, says: The property of the Christy S. M. Company, at Silver Reef, was not sold on the day advertised, as the company have made arrangements to settle all indebtedness and resume work. Capt. H. S. Lubbock, Supt., is expected to arrive at Silver Reef at any moment. The Reef still lives.

THE SWANSEA.—Yesterday a fine body of ore carrying 40 per cent of copper was struck in the Swansea. About two weeks ago this property was bonded to Mr. J. P. Ewing, of San Francisco, by Dr. Sarchet, J. C. Baker and Wm. Thompson. Mr. Ewing put in a steam pump immediately, and commenced sinking in the old shaft. At the depth of 105 ft a vein of two and a half ft in width, sampling as above stated, was struck yesterday. Mr. Ewing is to be congratulated upon his fine prospects. The mine lays directly east of the Colusa and in a belt that has not yet failed to develop good mines when depth was attained.

CHICAGO FRASER & CHALMERS. ILLINOIS

MANUFACTURERS OF IMPROVED AND APPROVED FORMS OF MILL AND MINE MACHINERY.

Having made extensive additions to our Shops and Machinery, we have now the LARGEST and BEST APPOINTED SHOPS in the West. We are prepared to build from the Latest and Most Approved Patterns.

QUARTZ MILLS

For working gold and silver ores by wet or dry crushing. The Stetefeldt, Howell's Improved White, Brunton's & Bruckner Furnaces, for working base ores. Rotary Dryers, Stetefeldt Improved Dry Kiln Furnaces.

SMELTING FURNACES,

Water Jackets, either Wrought or cast Iron, made in sections or one piece, either round, oblong, oval or square. Our patterns most extensive in use. SPECIAL FURNACES FOR COPPER SMELTING. Slag Pots and Cars, Improved form. Bullion and Copper Moulds and Ladles, Litharge Cars and Pots, Cupel Furnaces and Cars.

HOISTING ENGINES

Large or Small for flat or round rope. Double Cylinder Engines, from 6x10 to 18x60. This latter size furnished J. B. Haggin or Giant and Old Ahe Co., Black Hills also Corliss Pumping Engines, 26x60, for Hoisting and Pumping Works, for 2,000 feet deep. Baby Hoists for Prospecting, 4 H. P. to 6 H. P.

Wire Rope, Safety Cages and any Size and Forms of Cars. McCaskell's Patent Car Wheels and Axles—Best in Use.

Principal Office and Works, Fulton and Union Sts., Chicago, Illinois.

Frue Ore Concentrator, or Vanner Mills.

Coarse Concentrating Works, Improved Jigs, Crushing Rollers, Sizers, Trommels, Rittenger Tables, and all other adjuncts for the proper working of Gold, Silver and Copper Ores, complete in every detail. HALLIDIE IMPROVED ORE TRAMWAYS. We refer to Gen. Custer mine, Idaho, 5,000 feet long; Columbus Mine, Col., 4,750 feet long; Mary Murphy mine, Col., 5,000 feet long, all in constant operation.

LEACHING MILLS,

Improved Corliss and Plain Slide Valve Meyer's Cut-off Engines.

CORLISS ENGINES from 12x36 Cylinders to 30x60. PLAIN SLIDE VALVES from 6x10 to 36x36. BOILERS of every form, made of Pine Iron Works C. H. No. 1 Flange Iron, or Otis Steel. Workmanship the most careful. All Rivets Hand Driven.

PATTEN'S CONCENTRATOR AND AMALGAMATOR COMBINED.

This machine requires less power, less care or attention, and is less liable to get out of repair than any concentrator now in use. All of which any practical miner will comprehend when seeing it in operation.

The wear and tear is nominal, and the construction so simple that any miner can put it up and run it; and the low price brings it within the reach of all mill men, as it will save enough to pay for itself in any mill in a very short time. One machine will concentrate the tailings from a five-stamp battery.

The undersigned is now located at the Elva Iron Works, 217 to 221 Fremont street, where he is building the above machines and prepared to fill orders, and guarantee them to do all that is claimed. Weight 625 pounds, price \$300.

Estimates given and orders promptly filled for all kinds of Mining Machinery.

Assays and practical working tests made of ores.

C. W. PATTEN, 217 Fremont Street, S. F.

JAS. LEFFEL'S TURBINE WATER WHEEL, The "Old Reliable,"

With Important Improvements, making it the

MOST PERFECT TURBINE NOW IN USE,

TO HYDRAULIC

MINERS:

THE ABOVE CUT REPRESENTS OUR NEW IMPROVED GIANT, which we recommend as being the Best Hydraulic Machine ever manufactured. They are SIMPLER, LIGHTER, CHEAPER AND MORE EASILY WORKED than any style heretofore made. The machine is fully protected by patents owned by us, and we will guarantee protection to our customers.

Send for Circular and Price List.

HOSKIN & CO., Marysville, Cal.

JENKINS PATENT VALVES.

Gate, Globe, Angle, Check and Safety.

Manufactured of BEST STEAM METAL. We claim the following advantages over all other Valves and Gate Cocks now in use:

1. A perfectly tight Valve under any and all pressures of steam, oils or gases.
2. Sand or grit of any kind will not injure the seat.
3. You do not have to take them off to repair them.
4. They can be repaired by any mechanic in a few minutes.
5. The elasticity of the Disc allows it to adapt itself to an imperfect surface.

In Valves having ground or metal seats, should sand or grit get upon the seat it is impossible to make them tight except by regrinding, which is expensive if done by hand, and if done by machine soon wears out the valve, and in most cases they have to be disconnected from the pipes, often costing more than a new valve. The JENKINS Disc used in these Valves is manufactured under our 1880 Patent, and will stand 200 lbs. steam. Sample orders solicited. To avoid imposition, see that Valves are stamped "Jenkins Bros." For sale by

Dewey & Co.'s Scientific Press Patent Agency (Established 1860.)

INVENTORS on the Pacific Coast will find it greatly to their advantage to consult this old, experienced, first-class Agency. We have able and trustworthy Associates and Agents in Washington and the capital cities of the principal nations of the world. In connection with our editorial, scientific and Patent Law Library, and record of original cases in our office, we have other advantages far beyond those which can be offered home inventors by other agencies. The information accumulated through long and careful practice before the Office, and the frequent examination of Patents already granted, for the purpose of determining the patentability of inventions brought before us, enables us often to give advice which will save inventors the expense of applying for Patents upon inventions which are not new. Circulars of advice sent free on receipt of postage. Address DEWEY & CO., Patent Agents, 262 Market St., S. F.

Mining Share Market.

The main topic of interest in connection with the stock market is the combining of work of several companies to prospect at one point—the Mexican winze. The business men at Virginia do not like this very much because it causes the "knocking off" of a number of miners, but it will doubtless be best in the long run for the stock market and for shareholders. The *Enterprise* says: Had the masses thoroughly understood the meaning of the new plan of prospecting, there would have been no alarm to subside, as there was really no cause of alarm. However, any change from the beaten path is made cause of alarm, both in mining and governmental affairs, by petrified conservatives. Had the northern companies continued drifting about in the neutral straits above ad infinitum, the conservatives would have viewed the operation with perfect complacency, if not with an occasional feeling verging upon enthusiasm. Now, when the companies in question determine to go at once to the core and heart of matters, these men are disturbed; their easy, old-time equilibrium is shaken. However, all this will be forgotten the moment any decided improvement is announced in the Mexican deep winze—the deepest vertical excavation on the face of the earth.

At Gold Hill all is now going on well, and a large amount of ore is being extracted and milled. At the south end nothing is being done save in the Alta, at which mine they have started in to solve the problem as regards the country to the west at the depth of 2,150 ft.

Hill's Triumph Ore Mill.

The following statements concerning the Hill Triumph Ore Mill, will be of interest to quartz miners:

SONORA, June 8th.
 Mr. F. A. HILL:—My visit to the Pampa Hill mine yesterday to see your new mill worked pleased me very much. It is the best I have seen. I have been engaged in milling silver and gold ores for the past 15 years.

HENRY MEDICOT.

GRASS VALLEY.
 Mr. F. A. HILL:—As to my impression of your mill, I will say, it does its work well; and from its simplicity, the small power required to run it, the quantity which will work, and the price it can be sold for, the small expense to put them running when on the ground, makes me think they will prove the best thing I have seen.

STEVE MOORE.

SONORA, June 8th.
 Mr. HILL:—Our visit to the mine yesterday to see your mill worked pleased us very much. The mill seemed to do as much or more than you have claimed for it, considering the work it will do, and cost of machine. It is a valuable invention, and we are pleased to congratulate you on its success.

A. J. SWETSER,
R. B. LANK,
J. MILLER.

GRASS VALLEY, May 8.
 F. A. HILL:—In reply to your inquiry of my opinion of your new mill, I am pleased to say, after a careful examination and watching it work, I think it a wonderful success. The machine I saw, with very little power—no more than four horses—crushed as fast as a 10-stamp battery. I worked in an 8-stamp custom mill, in every capacity, for over 8 years.

CHAS. W. KITT.

SAN FRANCISCO, May 15th.
 F. A. HILL:—After having seen fully 1,500 pounds of granite fed through the rock breaker into your new mill and come out through a No. 7 screen within an hour, we feel justified in saying that the mill will do all you claim for it, in a most satisfactory manner. The construction seems strong and durable.

S. W. SHAW,

S. S. SWERTY, M. E.

COMPLIMENTARY SAMPLES OF THIS PAPER are occasionally sent to parties connected with the interests specially represented in its columns. Persons so receiving copies are requested to examine its contents, terms of subscription, and give it their own patronage, and, as far as practicable, aid in circulating the journal, and making its value more widely known to others, and extending its influence in the cause it faithfully serves. Subscription rate, \$3 a year. Extra copies mailed for 10 cents, if ordered soon enough. Personal attention will be called to this (as well as other notices, at times), by turning a leaf.

IMPORTANT additions are being continually made in Woodward's Gardens. The grove walked with aquaria is constantly receiving additions of new fish and other marine life. The number of sea lions is increased, and there is a better chance to study their actions. The pavilion has new varieties of performances. The floral department is replete and the wild animals in good vigor. A day at Woodward's Gardens is a day well spent.

ket St., S. E. Elevator, 12 Front St.

Iron and Machine Works.

MACBETH'S
—PATENT—
STEEL PULLEY.

Advantages of these Pulleys.

They are less than half the weight of cast-iron pulleys; are polished on the face; are made either crowned or straight, and are turned in the lathe the same as the best make of cast-iron pulleys.

They are carefully balanced. They are subject to no contraction strains, and can be run at very high speed without danger of bursting. On account of their great lightness and the form of the arms, they absorb less power than any other pulley. They are the only pulley of the kind which runs true. They cannot be broken in transport.

TESTIMONIAL:

MATHER LANE SPINNING CO. (Limited),
LONDON, ENGLAND, Nov. 5, 1883.

N. Macbeth, Esq., Dear Sir: The Patent Steel Pulleys supplied throughout to our No. 2 Mill are working to our entire satisfaction.

They are very true, and are about 50 per cent lighter than the cast-iron pulleys in our No. 1 mill.

Yours faithfully,

For the Mather Lane Spinning Co. (Limited),
[Signed:] RICHARD T. MARSH,
Managing Director.

HEINE PATENT SAFETY BOILER.

RISDON IRON AND LOCOMOTIVE WORKS,

Sole Agents for the Pacific Coast,

Corner Beale and Howard Sts., San Francisco.

Economy in space and fuel. Safety at high
pressures. Freedom from scaling. Equally
adapted for power and heating purposes.
Especially adapted for mills, factories, hotels,
scores or any place where safety is a necessity.
Will work well with muddy water and any kind
of fuel.

TESTIMONIALS.

ST. LOUIS, MO., Sept. 25, 1883.

Messrs. Adolphus Meier & Co. GENTLEMEN:
We cheerfully certify that the "Heine Patent
Safety Boiler" put up by you in our establish-
ment has proved very satisfactory in its working.
The chief points of excellence in the "Heine
Safety Boiler" are its economy in fuel and space,
freedom from scaling, aptitude for power and
heating purposes, working equally well with clear
and muddy water. We warmly recommend it to
all using steam machinery. Yours truly,

ANHEUSER-BUSCH BREWING ASSN.

OFFICE OF Supt. of ROYAL RAILWAYS,
BERLIN, Sept. 23, 1883.

To Mr. H. Heine, Civil Engineer: In reply to
your inquiry of September 2d, we respectfully in-
form you that the three boilers unit under your
patents, under steam since September 25, 1881, at the Alex-
ander Place Depot, as well as the two at Friedrich Strasse
Depot, under steam since September 22, 1882, have given
good satisfaction, requiring no repairs whatsoever to date.
The internal cleaning of the boiler was always accomplished

with ease on account of the convenient arrangement of the
tube caps, the adhesion of scales being fully prevented
thereby, and the boilers kept in prime condition.

(Signed): BRAUCKE.

WATER JACKET
SMELTING
FURNACES

—FOR—

Galena Silver & Copper Ores.

The PACIFIC WATER JACKET SMELTERS embrace
many features that are entirely new and of great practical
utility, which are covered by letters patent.

No other furnaces can compare with these for dura-
bility and in capacity for uninterrupted work.

MORE THAN ONE HUNDRED of them are now runs
along the Pacific Coast, giving results never before
obtained as regards continuous running, economy of
fuel, grade and quality of bullion produced. We are
prepared to demonstrate by facts the claims here made.

These Smelters are shipped in a complete state, requir-
ing no brick or stone work, except that for the crucible,
thus saving great expense and loss of time in construc-
tion.

Complete smelting plants made to order of any capacity
and with all the improvements that experience has sug-
gested as valuable in this class of machinery. Skilled and
experienced smelters furnished when desired to a upon
tend construction and running of furnaces. Estimates
given upon application. Send for circular.

NATIONAL COMPRESSORS and ROCK DRILLS.**EDWARD A. RIX, Agent,**

18 and 20 Fremont St., - San Francisco.

ON SEPTEMBER 1, 1883, I RECEIVED

THE LATEST IMPROVED NATIONAL DRILL,

— WHICH —

Anyone, upon examining, will proclaim to be far superior to anything yet offered to the MINING PUBLIC in the shape of a ROCK DRILL.

CALL AND SEE IT OR SEND FOR CIRCULARS.

**PACIFIC MACHINERY DEPOT.****H. P. GREGORY & CO.,****Importers and Dealers in Machinery and Supplies.****Nos. 2 and 4 California Street, S. F.****SOLE AGENTS FOR**

J. A. Fay & Co., Wood Working Machinery.

Bement & Son's Machinists Tools.

Blake's Steam Pumps.

Perry's Centrifugal Pumps.

Gould's Hand & Power Pumps.

Perrin's Band Saw Blades.

Payne's Vertical and Horizontal Steam Engines.

Williamson Bros. Hoisting Engines.

New Haven Machine Co.'s Machinists' Tools.

Otto Silent Gas Engines.

Hoisting Engines of all Kinds.

SOLE AGENTS FOR

Sturtevant's Blowers and Exhausts.

Judson's Steam Governors.

Pickering's Steam Governors.

Tanite Co. Emery Wheels.

Nathan & Dreyfus' Oilers.

Korting's Injectors and Ejectors.

Disston's Circular Saws.

Frank & Co.'s Wood Working Machinery.

New York Belting & Packing Co.'s Rubber Belting, Hose, Packing, etc.

Ballard's Oak Tanned Leather Belting.

**BLAKE STEAM PUMP.**

More Than 16,000 in Use.

The Korting's Injector is the simplest, cheapest and best in use. Will draft its own water, hot or cold, and feed under varying pressure. Send for Circular.

**\$1,000 CHALLENGE!****PRICE REDUCED,**

Jan. 1, 1884, to FIVE HUNDRED and SEVENTY-FIVE DOLLARS (\$755.00).

**THE FRUE ORE CONCENTRATOR, OR VANNING MACHINE.**

OVER 800 ARE NOW IN USE. Saves from 40 to 100 per cent. more than any other Concentrator; concentrations are clean from the first working. The wear and tear are merely nominal. A machine can be seen in working order and ready to make tests at the office of Hunkley, Spiers & Hayes, No. 220 Fremont Street, San Francisco.

To those Intending to Manufacture or Purchase the So-called "Triumph" Concentrator, we Herewith State:

That legal advice has been given that all shaking motion applied to an endless traveling belt used for concentration of ores is an infringement on patents held and owned by the Frue Vanning Machine Company.

That suit has been commenced in New York against an end-shake machine similar to the Triumph, and that as soon as decision is reached in the courts there, proceedings will be taken against all Western infringements.

That we are and have been ready, at any time, to make a competitive trial against the Triumph, or any other machine, for stakes of \$1,000.

ADAMS & CARTER, Agents Frue Vanning Machine Co.

Room 7—No. 109 California Street,

SAN FRANCISCO, CAL.

January 3, 1884.

GEO. W. PRESCOTT, President.
RYING M. SCOTT, Gen'l Manager.

H. T. SCOTT, Vice-Prest and Treas.

GEO. W. DICKIE, Manager.
J. O'B. CUNN, Secretary.**UNION IRON WORKS,**

Office—61 First St., Cor. First and Mission, S. F. P. O. Box 2128.

— BUILDERS OF —

STEAM, AIR, AND HYDRAULIC MACHINERY.**Agents of the Cameron Steam Pump.**

SAN FRANCISCO, CAL.

MANUFACTURERS OF

RAILROAD AND MERCHANT IRON,

ROLLED BEAMS, ANGLE, CHANNEL AND T IRON, BRIDGE AND MACHINE BOLTS, LAG SCREWS, NUTS, WASHERS, ETC., STEAMBOAT SHAFTS, CRANKS, PISTONS, CONNECTING RODS, ETC., ETC.

Car and Locomotive Axles and Frames, and Hammered Iron of Every Description.

HIGHEST PRICE PAID FOR SCRAP IRON

Orders Solicited and Promptly Executed.

Office, No. 202 Market St., UNION BLOCK.

GOLD QUARTZ and PLACER MINERS'

Silver Plated

AMALGAMATING PLATES,

For Saving Gold.

Every description of plates for Quartz Mills and Wet or Dry Placer Amalgamator Machines made to order, corrugated or plain.

OVER 2,000 ORDERS FILLED.

The most extensive and successful manufacturer of these plates in the United States. Will fill orders for delivery in Rocky Mountain and Pacific Coast Mining States at lower prices than any other manufacturer.

Old Mining Plates Replated. Old Plates bought or gold separated for low percentage of result.

SEND FOR PRICE LIST.

SAN FRANCISCO PLATING WORKS,653 & 655 Mission St., San Francisco Cal
E. G. DENNISTON, Proprietor.**THE "DUC" BUCKET!**

Always First Premium in Competitive Trials.

Extra Strong and Very Durable.

Made of Best Charcoal Iron, Only One Seam. No Corners to Catch. Runs with Least Power.

BEST MINING BUCKET MADE.

H. P. GREGORY & CO., Agents, San Francisco.

PRICES GREATLY REDUCED.

IRON CLAD MANUFACTURING CO.,

22 Cliff Street, New York.

**SURVEYORS—INVENTORS.**

A. SCHURCH, Mathematical Instrument and Model Maker, 335 Bush street, S. F. Scientific Apparatus and Experimental Machinery at short notice.

INVENTORS. MODEL MAKER,

L. PETERSON, 258 Market St., N. E. cor. Front, up-stairs, S. F. Experimental machinery and all kind of models, tin, copper and brass work.
